An Architectural Causerie.

An Abstract Consideration of Design.

To define design is difficult — definitions as a rule are difficult, and when acccomplished more or less indifferent—but this definition of design is almost as difficult to state as design itself is to accomplish. A well-known French artist, venturing where angels might with reasonable caution fear to tread, tells us that design is the result of a fine evanescent spirit of originality working in conjunction with accepted historical precedents and under traditional and acknowledged standards of art. This is a very excellent start towards our end, but it does not go far enough: it does not give a hint as to what percentage of "fine evanescent spirit of originality" is to go with the historical precedents of the art, or how predominant the tradition is to be. The percentage of originality may be painfully small in some cases, infinitesimal in others. Still, the definition would allow it to be labelled design. Such an acknowledgment would make a pitiful lowering of the standards referred to, and therefore may in no sense be permitted, and we must seek for more light on the subject elsewhere. Above all, we must remember that as we are judging design—and design in its greatest sense enters only into the highest and purest forms of art—we must keep our standards on the hill-tops, and not in the valleys accessible to men.

I have heard it stated by an art teacher—who has been teaching long enough to have had all the enthusiasm beaten out of him, but who still obstinately refuses to have that natural process of disillusionment dealt out to him—that there is a strong vein of individuality in any boy if he is taken in hand early enough. He also claims that this individuality is but the beginning of that larger originality which shall hereafter produce design, if only trained properly. Of course he has his theories of proper training; very pretty theories they are, and much I should like to follow them out to their logical conclusions, but not here. You can glean proof for yourself by watching the boys at their work, or you can trust the good faith of the teacher, which latter course is advisable, and follow the various work of the students accomplished alone and unaided—that is, aided only indirectly by the teacher. The boys are mostly sons of artisans, craftsmen in various trades, without the faintest familiarity with the art-jargon of the South Kensington student. In fact, the teacher has a positive dislike to any other material with which to work.

Work can be seen which alone bears the seal of originality without the endorsement of the integrity of the teacher. I will not say the work will please everyone; it is so extremely strange, original to a fault, individual to a failing almost. The enthusiasm of the teacher is such, however, that he will trace a likeness between the work of some of his boys and quaint old Egyptian, Assyrian, and Asiatic art to which these boys could not possibly have had access. In this, as in much the teacher says, is a large element of truth; and it will be readily granted that the interest of his experiment is not lessened thereby.

SPRING HILL, BRISTOL. DRAWN BY W. LEE CLARKE.

To the complete satisfaction of a discriminating few, he has proved his case; and where does it lead us? That originality is a gift of Nature inherent in many when young. Then follows the natural question, Why not compass more design? And that is a question which may now be examined.

The art student nowadays has easy recourse in his studies to copies, casts, counterfeits and sometimes originals, of a great percentage of the notable art works of the world. The great sculptors are open to him; great painters display their hardly-won secrets, canons, and ideals to his gaze; the architecture of a thousand years and more rears itself up before his eyes; and the whole world-wide artistic pageantry of the centuries passes in review before him. What a heritage is his! What a wealth of treasure for his discriminating sense! And yet—alas! that it should be written—this priceless treasure of the ages, this peerless heritage, is often the cause of his artistic downfall. He becomes a slavish admirer of some part of it: he is of this school or of that, but rarely the founder, consolidator, and pioneer of his own school. He must attach himself to one or other of the ancient giants whom he can never reach, far less excel, until his art, enfeebled by copying, plagiarised by persistent reiteration, and disgraced by slavery, becomes a commonplace, a nonentity, without style, without force, and, above all, without design. Such is often the result of a too close study of historic art. The greater the art, the greater the danger; for these ancients are so great, "they tease us out of thought," and the student must beware their fascination, must beware their charm, until he has built firmly upon his foundation of originality his structure of

design. Our definition tells us that for a work to enjoy the right of being called "design" it must show distinctive originality in conjunction with traditional and acknowledged standards of art; and how are we to judge this? Judgment, of course, will depend wholly upon the individual; but in this matter of judging, the greater the knowledge of the individual in historic art, the greater his capacity to seize the true quality of the design. For to design in any "school" of art, it is not only necessary to reproduce the character and feeling of such a school, but to instil new ideas, make new progress, while maintaining throughout the traditional character and style of such art. Therefore it will follow, the greater the knowledge of the tradition the greater the capacity to judge the advance over and above that tradition. When any "style," as we call it in architecture, or any national, historic, or particular art no more allows progress in its development by its exponents, it has lost its vitality, lost its real utility for the human race, and should be discarded. *The* test for this lies in this judgment of design. If the new work can honestly claim that name, it is progressive; and if not, it is the opposite; and the opposite means feeble and degenerate art. Let us take for example the pre-Raphaelite Dutch painters. Their style was pronounced enough, but it in no way precluded the painter from introducing his special scheme of design; his individual originality came out in spite of the school and the tradition, and not because of it. With a painter it is most imperative that he should have this quality of design. Painting Nature as he does, he cannot paint her whole unless he would use the globe itself for canvas—he must paint her in part. Yet Nature's own design for that part is relative to the whole, which his painting cannot portray; therefore, as he cannot seize Nature's own scheme of design, he has to make his own, which shall reflect that of Nature. In reality, his ideas are from Nature herself. This design and its quality lies in the truth, in the excellence with which he reproduces the unbounded scheme of Nature on the small finite square of his canvas.

Now how to gain this "illusive evanescent quality of design"? We see that a too slavish adoration of the ancients will not give it; that a too indiscriminate study, however enthusiastic, leaves us lost without it. Well, I may only give an individual conviction, in no way a universal belief, as to how it is to be attained. A surveillance over precedents, a stern judgment of the value of artistic convention, and a rigid adhesion to any quality of imagination and originality we may possess, will carry us far; but in the main back we must go to Nature. Back we must go to the fields for our conceptions, to the intricate tangled hedgerows, the many-wooded uplands, and the great cloud capes and promontories of heaven. The inspiration we require for our art, the knowledge, is not to be found in the master-brain of a studio-worm fixedly regarding his plaster wall for happy thoughts. Then, when the artist shall make his bid for refinement, shall wish to qualify for artistic culture, he shall look upon the world's artistic record without fear of numbing enthralment or danger of historical distraction. F. B.

Spring Hill, Bristol. To the casual man Spring Hill, Bristol, is but a short cut from the suburbs of Kingsdown and Redland to the City, and it probably causes him no second thought as he hurries to and fro in his daily journeyings; that it possesses more than passing interest is, however, apparent from the sketch by Mr. W. Lee Clarke on the previous page.

On Reflection.

Church Competitions. We print on another page the able address delivered by Mr. E. S. Prior at the recent Church Congress held at Newcastle-on-Tyne. The reiteration of the truth that the architecture of to-day is feeble and devoid of originality has become somewhat wearisome now, and it is therefore refreshing when someone takes up a new line of thought or makes specific charges against specific practices. We agree with Mr. Prior when he says that modern church architecture is the least real, the least progressive, and the least conscious of practical purpose; and that more than half of the large amount of money put into church-building during the last fifty years has been "work of supererogation in adding decorations and ornaments of Gothic and other copied styles outside the practical necessity of accommodation." But for the moment we would draw attention to his remarks about church competitions. The subject of competitions, though a hackneyed one, is nevertheless still a most important one; for, despite all that has been said against the way in which they are generally conducted, competitions are numerous, unsatisfactory in many instances, and capable of exerting a most baneful effect on architects and architecture. Mr. Prior cites the case of a church competition in the South of England which attracted 150 competitors. For the sake of argument it is assumed that six weeks were occupied by each competitor on his design, giving an aggregate of forty years' work occasioned by this competition. Now as only one competitor—the successful one—received any remuneration for his labour, the question may reasonably be put, What of the remaining 149 competitors who were unsuccessful, and therefore unpaid? It is futile to reply that they all entered on the same footing and took their chance, because the profession of architecture is not a polite form of gambling. Also, the argument that all the competitors were commissioned, so to speak, and submitted designs just as an architect might submit a design to a client, will not stand. In the latter case there is every probability that the architect will have the carrying-out of his design, though the client may wish certain alterations to be made first; whereas in an open competition it is only the authors of the successful designs who are rewarded. And this brings us to another point, that of the competition drawings themselves. It is now the practice for the work of selection to be done by an assessor, who, being at least able to grasp the appearance of a building from geometrical drawings, needs not the usual architectural perspective. We say "usual" because this is generally a drawing which boasts the qualities of prettiness and over-elaboration. If there is no assessor, and the selection rests with, say, a building committee, it is only fair that a pictorial view should be included with the designs; but the fault is that architects pander to the ignorance and lack of taste often characteristic of committees, and instead of submitting a perspective done with breadth of effect, and showing the building as a mass—supplemental to the geometrical drawings—they make one which gives every little angle and corner, and every bit of ornamentation, with microscopic definition; and to this picture all the really architectural drawings are made subservient. Unfortunately, competitions have fostered the detailed perspective, putting draughtsmanship before design; and this is perhaps one of the worst evils which the competitive system, so strongly denounced by Mr. Prior, has introduced.

Stained-Glass Windows. Mr. Selwyn Image's paper on stained glass, which appears on another page, commends itself by its advocacy of present-day themes of design and its condemnation of the trade-artist. The fact cannot be too strongly urged that it is better for a building to have no decoration at all than to have bad or paltry decoration; better for the windows to be glazed with good plain glass than to be filled with tawdry designs carried out in a manner worthy of a successful music-hall or a first-class hotel. Mr. Image insists that a stained-glass window should be regarded as a piece of fine art, just as much as a picture; and instead of bringing its cost down to the level of the available purse, we should be content to wait till the purse was full enough to pay for a good window. To take a case in point. A clergyman has a range of windows in his church filled with plain or tinted glass, and he desires to replace them with stained-glass windows. Now, considering the means at his disposal, he is generally in much too great a hurry to fill those windows, with the result that within a short time St. Johns and St. Pauls stand there in stained glass to memorialise the departed. They are probably not very expensive, and not very good; with the result that, instead of enhancing the appearance of the church, new features have been introduced which to any artist would be displeasing. According to our view, not only is the modern art of stained glass deficient in design, but there is far too much mixing of colours, which gives to the finished window a restless and spotty effect. What is badly needed is a greater use of colour in mass. Designers seem to be afraid to do this, though there are numerous examples—like some in Glasgow Cathedral—of windows of this kind to testify to the excellence of the principle, which, by the way, is also applicable to the laying-out of flower beds. Sir William Richmond's windows in St. Paul's Cathedral lack to some extent this broad effect of colour, and they are consequently less effective than they might be. Next to the method of supplying stained-glass windows at so much "per square foot," we think that this wholesale mixing of colours, this "crazy patch-work" form of design, requires reforming, and its place taken by something more artistic, more harmonious, and more beautiful.

Architectural Education. If a man is ever to do anything really great he must have an ideal, and this truism is particularly applicable to artists and architects. The ideal architect of to-day would be one who combined with the ability to design, to construct and to draw, the business capacity so essential to modern success. We have all around us engineers whose work, constructively excellent, drags architecture to a low level, and architects who should be ashamed of the inexcusable ignorance of true construction displayed in their designs. This is, of course, the result of a one-sided view of things, the result of an inability to appreciate beauty on the one hand and the neglect of the material on the other: a view which is the outcome of imperfections in our technical and architectural education. The suggestion is made that there should be established in this country a purely architectural college controlled entirely be experienced architects for the better training of architects. This proposal deserves support. We badly need a proper system of architectural education. Khartoum is being rebuilt by Royal Engineers, and the question—what training in architecture do Woolwich and Cooper's Hill and other colleges afford?—has its negative answer. Perhaps one day it will be generally recognised that architecture is not only a thing of strains and stresses, but one demanding the quality of fitness and beauty.

NEW YORK OFFICE BUILDINGS.

By W. G. P.

DURING Li Hung Chang's visit to New York it was observed that the Chinese statesman manifested great interest in the enormous "skyscrapers" which have grown up within a comparatively small area of the city, lying at the lower end of Manhattan Island. And to all newcomers from "foreign parts" they form objects of striking interest, if not of admiration. The European architect who sees them for the first time, and who probably approaches them with a mind biased by Old World veneration for the ethics of truthful building construction, and whose range of architectural criticism has hitherto been confined to buildings with a wall-head line of not more than 100ft. or so in height, finds that he has new subjects to examine, and that in order to come to a just conclusion as to their merits as architectural structures he must acquire some knowledge of the conditions which have guided and controlled the processes of designing and erecting them. Though, perhaps, disposed to view them at first sight with an interest similar to that in which surgeons examine a human monstrosity, he finds on closer inspection that many, especially the more recent productions, are pleasant to look upon, well proportioned, and composed of such excellently designed features, that he pauses and asks himself whether, after all, this "monstrosity" is other than a sudden and great development of the architectural species on a scale to which he is unaccustomed. He will disregard as "freaks" a few which are ill-proportioned and remarkable only for their size, and artistically useful only as warnings to future producers. The more he examines the buildings and acquires information as to their construction and erection, the higher will rise his admiration for the pluck and enterprise of the architects, engineers, and builders, whose combined skill and energy have quickly solved the problem imposed upon them by the capitalist, of erecting safe buildings of twenty to thirty storeys in height. It is true that no new principles have been used in dealing with the problem, for the engineer of twenty years ago would never have doubted the possibility of constructing these huge steel cages which form the skeletons of the structures; but he would certainly have regarded a demand to supply the parts for constructing one over 200ft. high within such space of time as would allow the entire building to be finished within twelve months' time as rather a "large order."

To the architect the problem presented has been, in the first place, to provide on a given site a floor area double, or more than double, in extent that which had hitherto been considered practicable. The demand for this arose from the desire for centralisation which in New York is peculiarly urgent owing to the narrowness of Manhattan Island at the lower end, in which part the centre of commercial activity is located. The Wall Street brokers, the banking and insurance companies, shipping agents, and professional men all desire to have their offices in that comparatively small triangular piece of the island which lies below City Hall Park, and the nearer to Broadway the better. The demand raises the price of land, which in this district varies from $150 to $250 per square foot, and the architect is called upon to provide sufficient floor space to yield in office rentals a proper return for the outlay on this and on the cost of erection. Each additional storey he puts up lessens the cost of site in relation to floor area, and after passing a certain point the construction of each storey is in itself less than that of those below. If the building rises to twenty storeys or more, the return increases sufficiently to yield a good margin for external architectural decoration as well as for internal finishings. By the erection of these huge offices buildings it is calculated that an addition of about twenty acres of floor space has been recently made in this part of the city.

One building alone, the new Bowling Green offices, has a floor area of 560,000 sq. ft., sufficient to hold, at the allowance of 4 sq. ft. to each person, a crowd of 140,000 persons, equal to the population of a moderately-sized town.

The most serious condition attached to the requirements laid before the architect is that the building shall be erected and entirely finished within the space of one year, so as to be ready for letting by May 1st following that on which possession of the site has been effected. This has been accomplished notably in the case of the Manhattan Life Building.

How, then, were the architects who first had this problem put before them to set about solving it?

In order to comply with the requirement of maximum amount of floor space, some means of reducing the thickness of walls had to be looked for. Under the system of self-supporting walls the base portions of walls for buildings twenty storeys in height would of necessity be built about 6ft. in thickness, to the great sacrifice of rental value, for every square foot of floor space is worth $1 to $2 of annual rent. The Chicago method of steel cage construction met the difficulty. It consists of a framework of steel standards, spanned by steel girders, further strengthend by ties and wind braces. The girders of each storey support the walls and partitions of that storey, and the weight of these is conveyed to the steel standards; and thus each storey of masonry or brickwork is independent of support from walls below, and a uniform thickness of walls and partitions can be used from basement topmost storey. This thickness can be reduced to the limit advisable for resisting weather and extremes of temperature, and thus the maximum of floor space is obtained. At the same time complete freedom of fenestration treatment is obtained.

In many cases a compromise has been used by making the steel framework carry only the floor and partition loads, the external walls being independent and self-supporting; but the advantage of this half-measure is not apparent, except that it allows of a genuine depth of reveal for façade features.

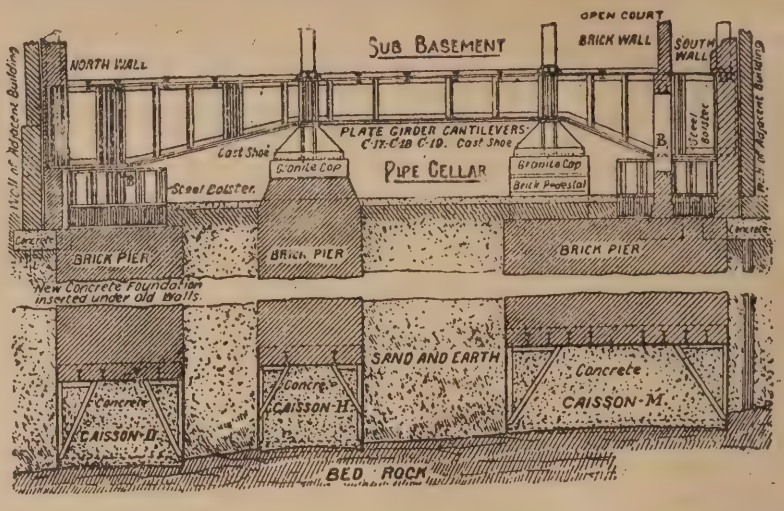
All steelwork is encased with terra-cotta or fireclay, for fireproofing purposes, by methods which will be referred to later.

Every opportunity of reducing the loads on the frames is taken by the use of hollow terra-cotta arching for floors and hollow brick or terra-cotta for partitions. The adoption of numerous lifts constantly running disposes of any difficulty in regard to access to the various floor and the upper floors are of equal rental

AMERICAN SURETY BUILDING, NEW YORK. BRUCE PRICE, ARCHITECT.
(STATUE OF PEACE BY J. MASSEY RHIND, SCULPTOR.)

value to the lower ones, and preferable on account of better light and air.

Thus in a practical common-sense way has the American architect responded to the demands of his financier client.



But how has the *art* of architecture fared in this revolution in constructive methods? The American Surety Building, when seen by the newcomer approaching the city on one of the great ocean liners, stands up in all its pure whiteness against the sky, which in New York has all the clearness, if not the intensity, of an Italian sky, and reminds him of an Italian campanile, the strength of its main horizontal lines, and the restraint shown in subordinating the treatment of the several storeys to the general design, giving an effect of dignified repose such as we have admired in Venice—and why not in New York? It is true that "there are others" (to use an Americanism), but the artistic success of this one building is sufficient to disprove any contention that such high structures must, *ipso facto*, be monstrosities.

It may be concluded, then, that so far as the eye can judge, this revolution in building methods is not detrimental to art. But what about the principles of æsthetic propriety in architectural construction? If we are purists and upholders of literal truthfulness in respect of architectural anatomy expressing itself in the external features, then we must own that the principle has suffered somewhat, for in these high piers of apparently solid masonry there is no suggestion to the eye of the steel-work hidden within; but if we are reasonably disposed to take into consideration the necessitous conditions absolutely imposed on the designers of "skyscrapers," our thought will be that in complying with these conditions the architect has fought a good fight for his art, and has achieved more artistic success than appeared probable. What result would purism lead to in the design of such buildings? Would it be considered necessary to expose the "altogether" of the steel uprights and girders, and to fill in the interspaces with metal plating, for consistency's sake? As reasonable would it be to form the internal wall surfaces of corrugated steel sheeting, instead of plaster.

But the discussion of this point has been long since done to death, and has not greatly affected the practice of architects. They must needs continue to comply with the demands of commercial requirements, well knowing that if they do not someone else will. We can all sympathise with that well-known architect who thanked God that he never had and never would use an iron beam or supporting pier in the construction of his buildings. He was fortunate in being able to preserve the moral rectitude of his principles of construction. But it is probable he was never asked to construct a building containing, in addition to public and executive offices for an insurance company, about 200 offices for general letting purposes, on a site 120ft. by 67ft., and to make the enterprise a financial success.

As an offset against this moral backsliding, if such it be, is set an advantage of some consequence to the appearance of the street façades. The margin accruing from the rental of offices is large enough to justify a considerable expenditure on the façade and such parts of the interior of the building as it is desirable to finish with some display of decorative completeness. Façades of white marble or granite enriched with carving and coloured marbles, internal screens, elevator frames, gates, and other finishings of bronze, brass, and wrought iron, and a generous use of marbles, onyx, and other rich stones, as well as of the finest varieties of wood for finishings, become possible. According to the writer's views, the loss in structural ethics is more than balanced by the gain in decorative resources.

Perhaps the point which amazes one "from the other side" most of all is the rapidity with which these buildings are erected. How does the architect produce his working drawings with the speed required to keep the works progressing without intermission? It seems undoubted that the drawing-office work is turned out more quickly than in British offices, and yet a similar supply of enlarged detail and full-size drawings is supplied to the contractor. The average draughtsman there is not better

SECTION SHOWING FOUNDATIONS OF THE MANHATTAN LIFE INSURANCE BUILDING, NEW YORK.

trained than are British draughtsmen. Probably there is proportionately a smaller number of first-class men in New York than in, say, London, though there are many draughtsmen who have been through the course of training at L'École des Beaux-Arts in Paris. But the secret must lie in good management. The offices are most commodiously arranged with the best appliances for the convenient execution of the largest drawings. The working plans are pencilled to a scale of ¼ inch to the foot, and then traced on cloth for reproduction by the blue process. The work is divided as much as possible, and in such a way as to employ each draughtsman, according to his special ability, on plans, sections or elevations, and ornamental details. An engineering draughtsman or an outside engineer is employed on the detailing of steel construction, and he and the architectural staff must work hand in hand. Many of the New York offices are large establishments, one firm employing between 50 and 60 assistants. There is always a clerk, often a gentleman of colour, to receive callers and apparently to prevent their access to the principals or to the drawing-office precincts.

The following printed notice, posted on the office walls of a well-known firm, is suggestive in relation to office discipline: "The hours for political discussion in this office are before 9 a.m. and after 5 p.m." An architect's office is not the only place where such a rule might with advantage be applied. Each office has its telephone connection and a few typewriters.

A description of some of the more recent buildings of this class will give some idea of their character. First, however, a few points noticeable in their construction.

Foundations.—The greatest care must of necessity be exercised in the foundations when such heavy loading is involved. Where not founded on a hard or firm stratum, piling or concrete with steel rails embedded in it is usually adopted. Where the latter is used, it is laid in several off-setting layers. The lowermost layer is of cement-concrete between 12in. and 24in. thick. On this are placed layers of steel rails embedded in concrete, each layer being laid transversely to that below and above; and on top of these is the cast-iron shoe to receive the steel piers. Where the position of piers is such that unequal distribution of loading is feared, compound foundations combining to support several bases are used, and various methods of cantilever form employed to distribute, and if necessary divert, the load. In the Manhattan Life Building, where it was necessary to start from the bed-rock, about 57ft. below the level of Broadway, pneumatic caissons of steel were used, in order to avoid injury to the walls of the adjoining building, which were founded on the natural soil at a much higher level. These caissons, varying in size from 9ft. in diameter to 25ft. by 21ft. 6in. and 11ft. in height, were filled with concrete, and the piers on them, up to the level of cast-iron shoes, were built of hard burned bricks with granite coping course. Steel cantilevers were employed to divert the loading from piers of side walls on to the caisson foundations, and thus all interference with the side walls was avoided. As basements for boiler and electric-lighting plants are necessary for these office buildings, excavation has to be made in all cases. The rock crops up to the surface in many parts of the city, and it is usual to see extensive operations progressing in the way of boring and blasting. The reports of dynamite may be heard all day long, even in the most populous parts.

Steel Piers.—Although cast-iron columns are still being used as the main supports in some buildings, the unsuitability of the material for use in frames 200ft. high or more is being recognised, and it will suffice to describe only some of the forms of steel columns employed. These are many, comprising various combinations of L plates, Z bars, H bars, circular, octagonal and box forms. The amount of labour involved in the putting together of these combinations is the chief factor in choosing a particular form. The form most in favour hitherto appears to be the Z-bar column, composed in its simplest form of four Z bars riveted together with a web plate, and with only two rows of rivets. This form is probably the cheapest and best where the sectional area thus obtained is sufficient for the strain to which it is to be subjected; but when a larger sectional area has to be obtained by the addition of cover plates and a larger number of Z bars, the amount of labour in riveting about ten or twelve rows of rivets renders it an expensive form for large columns. A form recently brought out, and known as the Larimer column, seems to be a more economical form for large columns. It consists of two rolled I beams, bent in the middle of their webs so as to form an L, and riveted together in the middle with a smaller I beam as filler. The base and cap plates are connected by riveting angle pieces to the outside flanges and to plates. With the same sectional area it is claimed that the ultimate strength of the Larimer as compared with the Z-bar column is as 37 to 31.

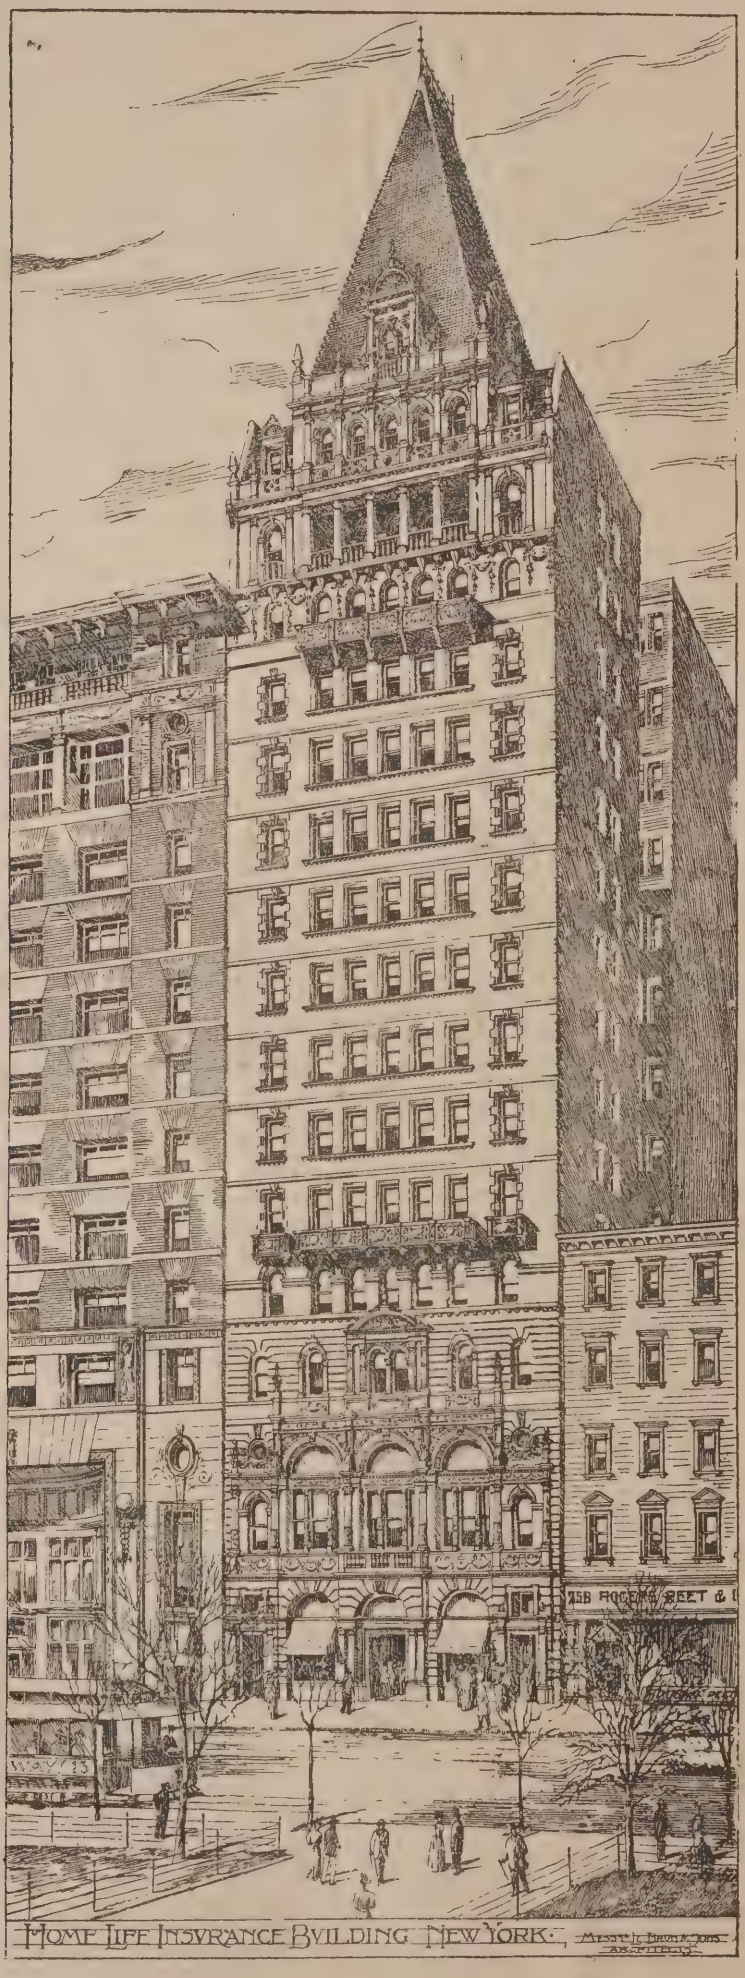
The columns are cased in terra-cotta or fire-clay tiling 2in. or more in thickness, and finished in plaster. The material which has proved most suitable for resisting heat and the application of water when heated is the porous tile rather than the hard-surfaced tile. The tiles are wired to one another and to the column with copper wire.

Floors.—The floors are generally formed of steel rolled beams spaced at from 4ft. to 7ft. centres with flat arches of hollow terra-cotta, springing from skewbacks resting on the flange of beam, and so formed as to encase the soffit of flange. Tie-rods connect the beams. A layer of concrete 3½in. thick is laid on top of arch to receive the finished flooring.

Spandrel Walling.—When each storey of walling is carried by the steel framing, the spandrel walling of stone or terra-cotta is connected to the girders by means of hooks, bolts, and cramps, as the section may require. Where the projection is great, steel cantilevers are projected from the main girders, carrying at

their outer end smaller beams T or L bars, as required to support the walling.

One of the best examples of a 20-storey building finished so far as to be ready for occupation within the space of one year is the Manhattan Life Building, designed by Messrs. Kimball and Thomson. Nearly the half of this time was spent on the foundations, in which occurred unforeseen difficulties; but the superstructure was then put together with such rapidity that in three months' time the roof or eighteenth-floor level was reached, and the offices were ready for occupation in less than seven months from the date on which foundations were ready, while the whole was completed one month later. Some figures will help the reader to realise the amount of work executed in this time. The concrete foundations contained 1,260 cub. yds. In the brick piers continuing these up to cellar level were 1,500,000 bricks. The Broadway front contains about 30,000 cub. ft. of masonry, which was cut and set in position in 80 days. More than 5½ miles of piping for gas, water, waste and vent pipes, 5 miles of steam pipes, and 35 miles of electric wiring were fitted up.



The style of the Broadway elevation is the Early Italian Renaissance. It is entirely executed with Indiana limestone. A huge archway, extending up through the two lowermost storeys, gives prominence to the entrance. In its design it reminds one of the west doorway of the Church of the Certosa at Pavia. The central composition continues up for two more storeys, when it finishes with a central-pedimented window. At a higher level a colonnaded treatment running through sixth and seventh storeys, with a projecting balcony underneath, produces a fine play of light and shade, and at the same time binds the front together at the point where the front is broken up into a triple composition continuing up to the top of building. The middle portion is recessed, and the projecting side portions carried up through main cornice and finished as pavilions with dome roofs. Over the middle portion, which is further recessed above main cornice, the composition is carried up higher, and finally finishes in a copper lantern of elegant proportions. The grouping of pavilions and lantern gives a most picturesque outline when viewed from any point from which the skyline of the back portion of building is not visible; but this building shares in the fault common to most of the skyscraper class in which a grouped skyline is obtained, in that little regard seems to have been given to their outline when viewed from a distance or from the rear.

The interior offices show some excellently-designed finishings in metal and marble screens, and elaborate wood and plaster work, all well worthy of illustration, but not coming within the scope of this article.

The Home Life Insurance Building is another example showing a picturesque skyline. It is finished with a high-pitched wedge roof covered with deep red tiles, with a most pleasing result. The general design of the façade is of a French Renaissance character, but the details of the façade are from the best Early Italian Renaissance sources, and have much refinement,

METROPOLITAN LIFE BUILDING NEW YORK. Messrs N. Le Brun & Sons Architects

if somewhat "petite" in scale. The three lower storeys which form a base to the façade are built with rusticated joints, forming a good ground to the richly-decorated fenestration applied thereon. The walling and fenestration above is severely simple, until broken by a richly-corbelled balcony and a deeply-recessed loggia stage under the wall-head. The contrast of light and shade thus obtained is heightened by the use of white marble throughout. The main dimensions are: Width 55ft. 6in.; height to top of stone gable, 237ft.; to top of spire, 280ft. The construction is of the skeleton steel and brick order, except the front wall, which is built of solid white marble, the joints of each course extending right through the wall. This method was adopted in order to avoid the danger of unequal settlement owing to rapidity of building, which would probably have occurred if brick backing had been used. There are 162 offices, arranged in suites, in addition to the company's offices, which are on ground storey and basement. Messrs. N. Le Brun and Sons were the architects.

The Metropolitan Life Insurance Building is another work by the same architects. It is also Italian Renaissance in style, though of a stronger type than the Home Life Building. The materials used are white granite from Maine, with brick backing for the exterior walls. The internal hall and staircase, which are of a most palatial character, are of local and Italian marbles, with onyx handrail, balusters, and pedestals, the metal work being of bronze and brass. The cove at ceiling is of coloured marble mosaic. The exterior façade finishes with a massive cornice of about 6ft. projection.

The building covers a site 145ft. by 125ft., in which the company's executive offices are placed on the first and mezzanine floors; while a large annexe, 100ft. by 115 ft., on Twenty-fourth Street, is entirely appropriated to the administrative department of the company. Steel beams and terra-cotta flat arches with cast-iron columns form the internal construction, the outer walls being self-supporting. The work occupied two years in erection and completion.

The American Surety Building has a frontage on Broadway of 84ft. 6in., with a return on Pine Street of 85ft. 6in., the plan being a parallelogram but little removed from the square. It has a total height of 308ft. from pavement to coping, embracing twenty-one storeys. The external walls are entirely faced with dressed Hallowell granite, and have a slight batter. They are for the first hundred feet about 4ft. in thickness, which is reduced as it rises, the average thickness being 2ft. 4in. The walls do not carry the floor loads, which rest on steel supports encased in the walls. The treatment of fenestration is interesting, in that the lower-storey windows have the shallowest reveal, thus giving the maximum of light where it is most needed, and the depth of reveal is increased gradually towards the top, so that the glass plane inclines inwards from base to top, producing an effect which gives a subtle aid to the perspective.

In style, the details of the tower—for such the whole building may be termed—are Greek. The two lower storeys on the Broadway façade are combined in a hexastyle Ionic portico composition, with details reproduced from the Erectheion at Athens. The details of capitals and other carved enrichments are exquisitely executed, and have all the refined spirit of Greek art. Over the colonnade is a Greek attic, with a row of allegorical figures designed and carved by Mr. J. Massey Rhind, a Scotch sculptor of Edinburgh, and a brother of J. Birnie Rhind, A.R.S.A., of that city. The figures symbolise the various virtues which a charitable age accepts as controlling commercial success. At once stately and pleasing, calm rather than severe in conception, the figures draped with simple restrained lines harmonise perfectly with their architectural surroundings, and may be truly regarded as architectural features. The whole composition of these lower storeys, which forms a podium to the superstructure, has a rare effect of unity and dignified repose. Within the portico is a hemicycle with a radius of 19ft. and a height of 32ft., with a doorway on each side entering into the banking rooms, and a central one into

main building. The walling above the third storey is treated with granite courses, each alternate course recessed. The windows have moulded architraves, and the angles are formed with rusticated quoins. With the exception of one string course above the fourth storey the wall is continued up without any projecting band to the fourteenth storey, above which occurs a carved band. Considering the whole tower as a column, the fifteenth storey corresponds to the necking of capital, and the next four storeys above constitute the bell. This stage of four storeys is treated with a colonnade, in fine contrast to the comparative plainness of skill and gracefulness of line. They suggest French rather than Greek art, and in so doing soften the transition in style which occurs in the façade. The lower portion is pure Greek, while the upper stages are designed with considerable freedom of style in detail, though the general effect is that of Neo-Grec. These figures, as well as all other carved work, except the statuary before mentioned, were executed under the general granite contract by Mr. J. Pierce, New York.

The architect, Mr. Bruce Price, is to be congratulated on the production of a design having much originality, and in which the principle

the shaft below, and finishes with a massive and richly-detailed main cornice which has a projection of 6ft. Above is an attic storey, the skyline consisting of a row of Greek antefixæ in gilded bronze. The one enrichment to the shaft of the composition occurs at the fourteenth and fifteenth storeys on the Broadway front, and is an excellently-designed central group of two classically-draped female figures clinging to the sides of an oval window which is the central feature of the fifteenth storey and extending down to the sill of the fourteenth storey, terminating there in voluted scrolls. The figures are modelled and carved with much of unity has been successfully carried out. The time occupied in erection was 175 days.

The foundations start from the bed-rock, about 70ft. below Broadway, and the pneumatic caisson system was adopted. One of the foundation columns is capable of sustaining a load of 1,685 tons. The total estimated load on the foundation is 25,000 tons or 7·2 tons per square foot. Four millions of bricks were used in the foundations, and an equal number in the external walls of the superstructure. The cubical contents of the building inside walls is 2,000,000 cubic feet.

The shell of the building is constructed on the steel-cage principle, with terra-cotta arching for floors.

It is satisfactory to learn that practically complete rigidity has been obtained in this huge tower, as the following quotation from a description published by the company will show: "During the height of a heavy storm, January 4th, 1896, when an official wind velocity of 82 miles per hour was registered, Mr. Rogers, the architect's assistant and superintendent of the construction of the building, and Mr. Wiegand, engineer of the Jackson Architectural Ironworks, made a test with transit and level, and were able to discover only one-sixteenth of an inch vibration in any part of the building, though the estimated pressure on the whole front at the time was 332 tons, and the bending or overturning moment over 52,000 tons, which gives an impressive idea of the solidity of the construction."

Mr. Bruce Price's design for the Sun Building is modelled on the lines of the Campanile of St. Mark at Venice. It is higher than the American Surety Building

Many other "skyscrapers" are in progress and on paper, some more than thirty storeys in height, and many worthy of special notice, such as the Bowling Green offices, by the Messrs. Audsley, a building whose details recall the works of "Greek" Thomson in Glasgow; but space forbids.

ARCHITECTURE IN RELATION TO RELIGION.*

By EDWARD S. PRIOR.

I TRUST that the speakers who have so ably represented painting and sculpture (see p. 172 of last week's issue) will not suspect me of disrespect to their arts when I pointedly speak of architecture as the *practical* art. As regards painting and sculpture, the relations of these to the Church may be ideal—those of happy fortune—and if there have been moods of caprice, in which painted and carved imagery has been repulsed and chided instead of fondled, it has been as the "falling out of faithful friends" with ever a *redintegratio amoris*. But for architecture there has been a constant, though only prosaic, link of a practical necessity—architecture has necessarily been church-building, and the Church has not been able to say to the builder "I have no need of thee." And I take this practical quality of architecture as my text—upon this platform let the art of building come into relation with religion.

I had the advantage this summer of hearing two great speakers of our Church refer to the connections of religion and architecture. The Archbishop of Canterbury eloquently described the effect of great church-building; how its contemplation lifted the heart of the worshipper; what suggestions of reverence grew out of its ordered immensity; the still voice of its perpetual preaching. Far be it from me to deprecate this conception of architecture, or to minimise what is a genuine practical quality of its expression. The Bishop of London, who followed him, went further, however; he suggested that architecture found its ideal in church-work because that alone could lift it above the drudgery and meanness of everyday needs. And, further, that it is by the association of painting and sculpture in their buildings that architects must make good their claim to be artists.

Now this was sad hearing for architects: my art of architecture was put in a false positin false historically if I might say so to an historian, for never in history has architecture been an art save by its own quality of practical building. And neither to the Church on the one hand, nor to painting and sculpture on the other, has it owed this quality.

And depressing, too, was the Bishop's suggestion in its bearing on the work of to-day. His words were perhaps half ironical, but the

* Speech before the Church Congress at Newcastle-on-Tyne, September 26th, 1900.

suggestion made, that architecture can be an art outside its practical use, is what perpetuates its degradation. While it is taken that the Church can supply an ideal or style to building, and sculpture and painting can make decoration, and so that it is made art, which without these is only practical ugliness, so long as this idea is abroad must the Church miss the meaning of architecture: and make no good use of it.

While it may be a question whether art *can* come into definite relation with religion, it can be no question that such relationship must base itself on real expressions, not on false ones and make-believes. Yet, if we look at the building work of to-day, one can only observe that church architecture is of all the least real, the least progressive, and the least conscious of practical purpose. The amount of money and design that has been put into church-building during the last fifty years has been very large, yet certainly more than half of this has been work of supererogation, in adding the decorations and ornaments of Gothic and other copied styles outside the practical necessities of accommodation. Yet no life of architecture, despite the expense and pains given, has been realised. Church-building has set no example; it has kept itself from no abuses; it has created no hope among artists and but little reverence. Is not this because it has missed the practical purpose of building which alone makes architecture art?

I go at once to the particulars. In how many cases has church-building sought the aid of architectural competition. There is nothing to be said against competition in the abstract, as one of the seeming laws of our existence. But an architectural competition is not one in real work, in building capacity, but in the presentment of it—the drawing of design. I am not concerned here with the abuses of honesty which have made architectural competitions a by-word; but with the practical futility of instituting a competition in one thing, the designing on paper when the thing to be selected is another, the ability of a church-wright. That there is a practical failure in the method of architectural competition has been acknowledged for thirty years. It clearly proposes a false standard to its competitors, that of pleasing by representation, not by work. So far as they are architects, workers in building, they are degraded by forcing themselves under such a standard. Nor has the Church disguised its opinion of those thus invited to degrade themselves. The conditions of church competitions which have come under my eye are such that they express contempt; they have all the unfairness of the usurer's bond, giving nothing and taking all things — that legal security which the commercial sweater exacts from the victims of necessity. Under such conditions a church competition lately in the south of England proposed to spend £5,000. It obtained 150 competitors, and as six weeks of work would be necessary for each church design, 900 weeks (or about forty years) of useless unpaid work were spent; useless, for of what avail to this or any other church were the 149 rejected designs? The out-of-pocket expenses of the candidates probably exceeded the proposed outlay on the church.

Of course the Church does not realise this view of its competition procedure. It only does what others do: it takes what it can get. There is no compulsion on the architects to compete. So the usurer says: "The borrower signed the bond of his own free will." But the art of architecture does realise the waste, the low ideal, the practical futility of architectural competitions, and refuses to appear in competition churches. Let it be that money payment is never the payment of art, that the exercise of a man's faculties in a noble purpose is its own reward, that church design is such a purpose, and so is never wasted. So doubtless the Church thinks; but then let the Church honour this exercise. Does it do so now?

It has been too seldom that the proposer of church-building, rejecting the evils of competition and the status of professional business, has proceeded on the common-sense of selecting an artist whose art he perceives to be one of a personal ability in building. Still not seldom have parson and architect with one soul desired and spent themselves on the best expression of church-building that lay within their means; with such in its truest sense *laborare est orare*. But there succeeds to this inheritance another incumbent: is there any security that he will honour the good work done? It is notorious that the incoming parson has no scruples as to the *art* of the church to which he succeeds. He can transform it and ruin it as he chooses, feeling quite unbound by his predecessor's selection of architect; handing the building over to commercial firms or others to add furniture, glass, screens, and such like, which by the nature of their making cannot but be an insult to the real work of an artist. I know a case where the patrons of a living, the lay-rectors, had the scruple that what was well begun should not be ruined by irresponsible additions. They forbade the introduction of manifestly vulgar and manifestly unsuitable fittings into their church. But the incumbent was wishful for what was denied him, and went on a journey. The prohibited articles were smuggled into the church in his absence, so that he might have, but not know, and on his return plead the six months' use. Now, in thus getting furniture for his church by what in plain language was a trick he was applauded by his brethren, and the reason is clear. The patrons' control was considered unreasonable, for the architectural *art* of a church is in no honour compared with the ecclesiastical *style* of its fittings. However contemptible the art of such things, they were offered as gifts to the church, their donor had paid money for them, and this money's-worth of ecclesiastical style could not be refused. Such donations are the passport to the title of "good churchmen." I am not speaking without authority, for in the last six weeks has not a dean publicly declared that only subscribers to its decoration can be regarded as having any interest in a cathedral? And how often do we not hear it said by our clerical friends: "Yes, we in the charge of our churches know the value, and wish the religious expression of real art. But what are we to do? Our people will give us what they can see in the shop window, or pick out from a tradesman's catalogue. We know such things are contemptible, but can we refuse them?" No, you cannot refuse if you do not feel that religion is hurt by a false art of church-building and church-fitting; if you think it no great matter that the artist cannot enter a church except with repulsion, that he must hide out of sight of the chancel and come to the altar with averted eyes. Yet there is a larger body than, I think, the Church understands who are sensitive, whose consciences are troubled when they see the decorations of a church to be very much those of the restaurant or music hall, redolent of money and display, but with no heart, truth, or faith in them.

Ecclesiastical styles have made the cloak which has hidden this want of reality in our art, but that cloak is slipping away and showing what is beneath. Sixty years ago, in the fervour of the Gothic revival, while it was believed that the forms of ecclesiastical architecture made religion art, and when in this conviction was done earnest work by Pugin, by Street, Burges, and Butterfield, then churches could be built and decorated in Gothic style, expressing this conviction, and not merely as business forms. But how is it now? The life of Revival Gothic is manifestly over. Its forms are an avowed professional stock-in-trade, and can be manufactured at so much per foot by any and every firm of tradesmen; but the earnestness, the self-respect of architects will not have such things. For it is perceived that the truth of art cannot be expressed in copies, in stereotype, in what can be stamped out by a machine—human and mechanical—but can come only by the emotion of the artist, and in the experimental creation that emotion fructifies. We have made a dead Gothic; have made caricatures, because by the nature of things living art was impossible to us. And caricatures, when seen to be such, what can they be in a church but offensive? The reproduction of Romanesque, Gothic, and Renaissance church-building, the nearer it gets to the originals, the more exact it is, the more machine-like—by that very quality has become the more false in spirit, the fouler to the taste, the less fitted for religious use.

There are our old churches, where "restoration" has made this offence the greatest. And I speak here not only of the actual removal, but of the swamping of the true religious work of our forefathers, the contempt of it which our church additions show, so that in the last fifty years there has been wiped out that religious expression of the Gothic centuries (and of the seventeenth and eighteenth too) which in every church of our land forged a *catena sanctorum* —surely of value to the English Church—but now broken, its real links taken away and base metal substituted, so that there is scarcely a church left to us in which seven-eighths are not substitutions. The accomplished author of "Walks in Rome" speaks of what was till lately the best-preserved Saxon church in England, but now, he says, a "mere rebuilding" with "all that vulgar tiles, revolting glass, and coarse woodwork can give liberally bestowed." Of how many thousands of our churches must not this be said? Is there no other use of our old architecture possible but to make it a block upon which to exhibit the failure of Modern Gothic? When Edmund Street's nave to Bristol and Sir Arthur Blomfield's nave to Southwark are seen to be cold graceless works, doing no honour to the old work, is it proposed to add the same sham dead thing to Hexham?

This is no practical use of our present-day art of architecture, to bid it be untrue to itself and think not of its real function of building, but only how it can caper, as it were, and gesticulate in mimicry of artists long dead; now with cusps and crockets, and now with pilasters and friezes, now with traceried reredos or canopied baldachino, now with winged archangels and haloed saints, and now with *Amorini* and cherubs, pretending to emotions which it feels not and cannot feel, because they do not grow of its present needs. I believe that there are among churchmen, lay and clerical alike, many —I had almost said all who have thought on the matter—with the feeling that there should be building by the Church other than these forgeries of ancient church decorations, this burying of the history of the English Church, its love and its art under the ashes of "restoration."

I believe the haphazard system by which our churches get their building and decoration is largely the reason that this feeling has not prevailed to produce a true church art of practical building. A definite authority in the Church, advisatory and suggestive, with at least that standing which would have enabled it to review all church-building and all church-decoration, would have done a great deal to prevent the abuses of open church competitions and the neglect and contempt of existing church fabric, whether new or old; would have set at least a value on real art, by stating knowledge of its existence, so that it could not be removed or disfigured as a matter of course to make way for a rich man's gift. But the real hope for architecture—that it may again arise in the service of religion—does not lie in any established authority, but in a change of feeling; in the growing conviction that church-building should meet the practical necessities of accommodation with the common-sense materials of good building, and not with any copying of ancient models; for revivals and restorations are mimicking forms, but denying the spirit—the hypocrisy of art—and the hypocrisy of art is offence to religion. What was bidden to the feast would not come, for it was busy with ecclesiastical style, professional success, and commercial profit. Now art must be compelled to come in out of the highways and hedges of plain practical building and the plain honest love of the artist.

Proposed New Baths and Fire Station for Birmingham. — A Local Government Board enquiry was held last week with reference to the application of the City Council to borrow £12,100 for purposes of public baths, and £7,500 for the erection of a fire station in Saltley Road. There was no opposition.

Bricks and Mortar.

APHORISM FOR THE WEEK.

"The most difficult thing in all works of art is to make that which has been most highly elaborated appear as if it had not been elaborated at all."—WINKELMANN.

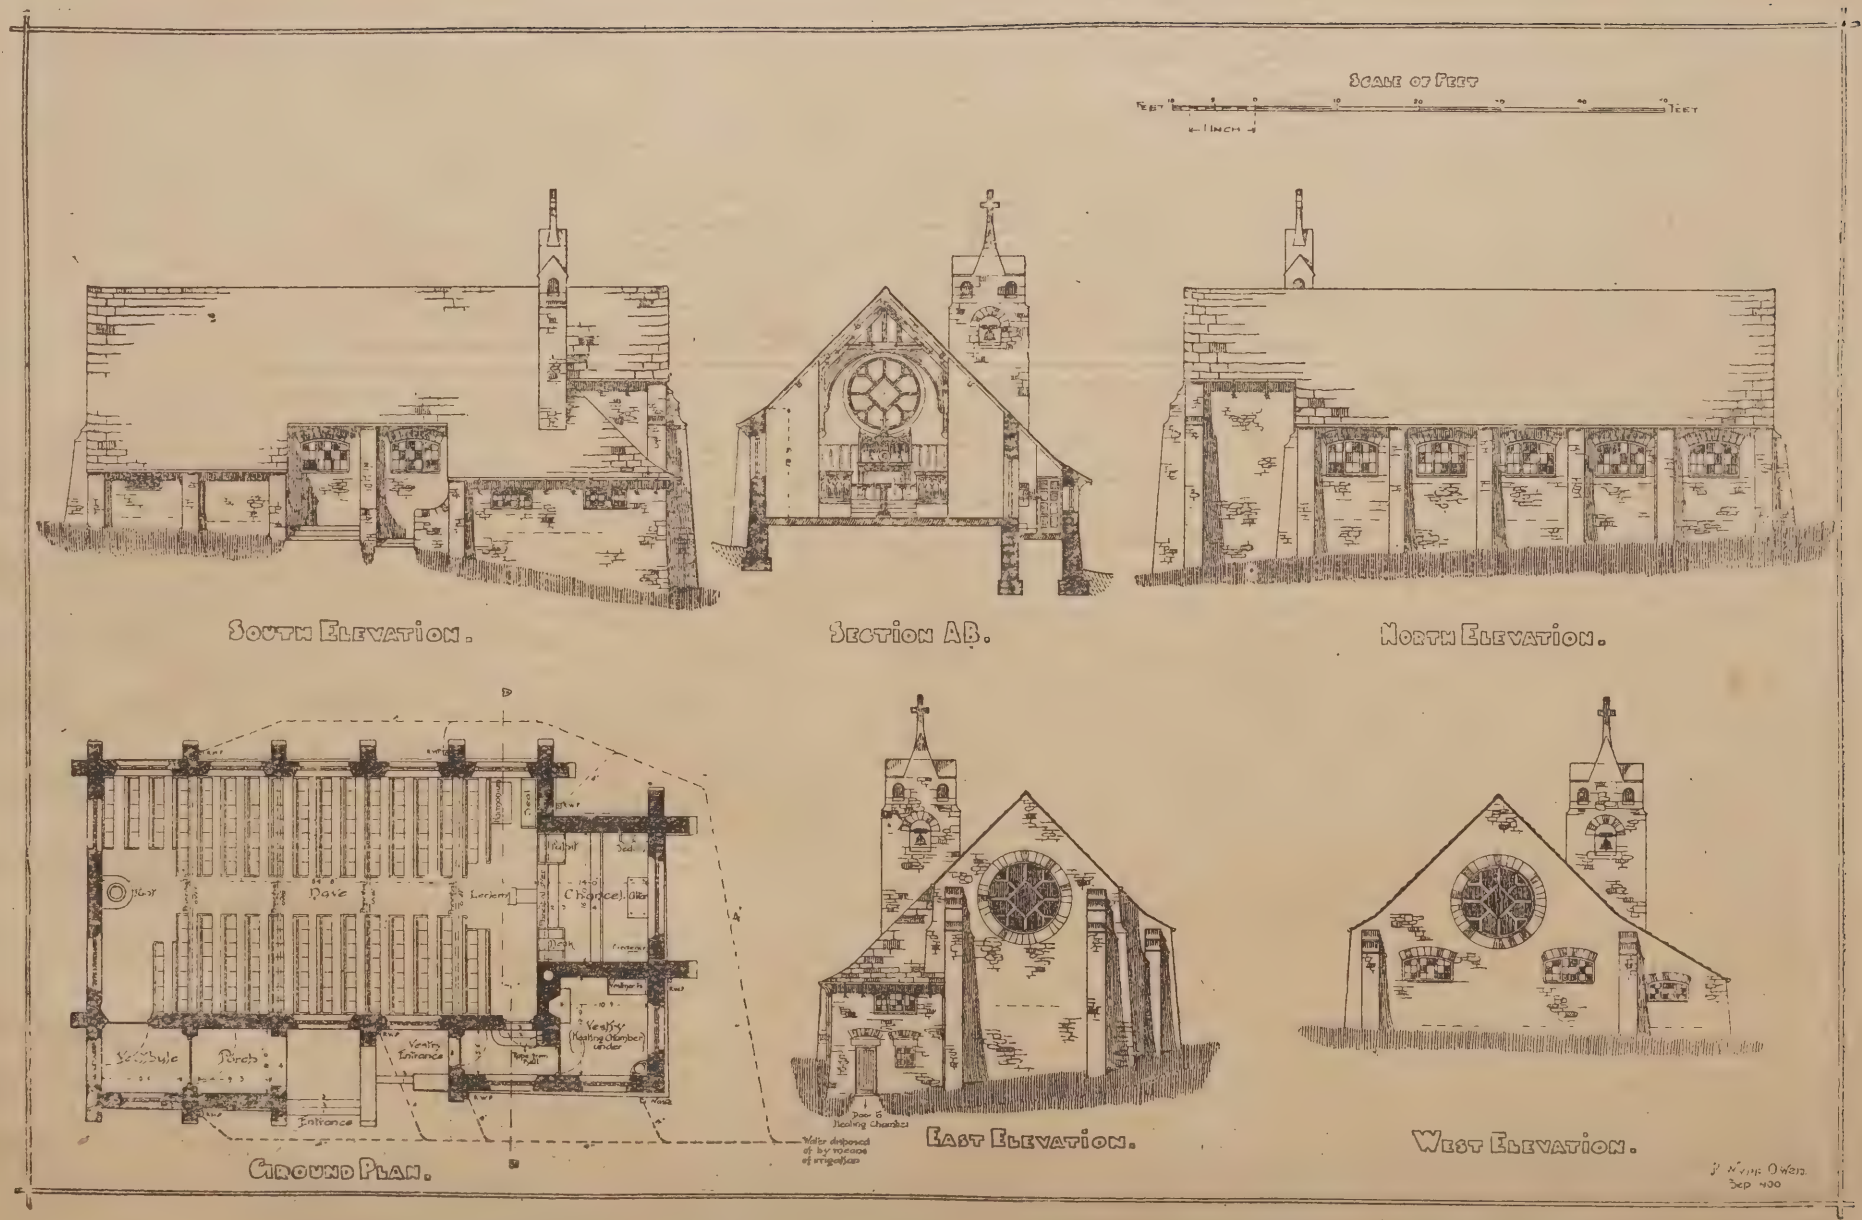
Our Plates. PARTICULARS of the mountain church design by Mr. R. Wynn Owen will be found on page 197 of the present issue. The bird's-eye view of numerous tall buildings on Manhattan Island, New York, forms part of the illustrations to the article on high office buildings which begins on page 183. Mr. Baillie Scott's design for the drawing-room at the Palace, Darmstadt, was exhibited at the Royal Academy in 1898. It is an admirable piece of work.

Welbeck Abbey. ON Friday morning last the Oxford wing of Welbeck Abbey (the Nottinghamshire residence of the Duke of Portland) was destroyed by fire. Extensive alterations were being carried out, and there was a large staff of men employed. The fire was discovered shortly after two o'clock, the flames being noticed by the night watchman. The alarm was immediately given, and the two steam fire-engines upon the estate were brought into requisition, and Sheffield was asked by telephone to send on one of their engines. This was done, a special train being employed for the purpose. The Worksop Fire Brigade was also summoned, and promptly responded to the call, but the flames spread with alarming rapidity. The work of the brigade was rendered very arduous by a strong breeze, which fanned the flames and threatened the other portion of the Abbey. All efforts were therefore concentrated upon limiting the area of the fire. It was not until eight o'clock that the fire was got under. The whole of the upper portion of the Oxford wing, which constituted the new storey of the south front, was destroyed. All the valuables and works of art were, fortunately, removed during the progress of the fire, great assistance in this direction being rendered by the miners from the neighbouring colliery. The damage is estimated at £25,000. Happily the magnificent Gothic Hall was not injured.

The Simplon Tunnel. AT the Simplon Tunnel there are now employed 3,000 workmen on the Swiss side and 2,500 on the Italian side. Nearly all of them are Italians. Two tunnels are being bored instead of one in order to avoid the possibility of collisions, the distance between the tunnels being 17 metres. The work must be finished, according to the contract, on May 13th, 1904. For every day required beyond that date, says the "Times," the contractors would have to pay £200 to the Swiss and Italian Governments; for every day saved the company will receive £200. The Gothard Tunnel, which is 15 kilometres long, took twelve years to bore. The Simplon, which will be 20 kilometres long (the longest in Europe), is to be completed in five years and a half. Nearly 3,000 metres have been completed on the Italian and nearly 4,000 on the Swiss side. The engineers guarantee that the junction of the two borings will be mathematically exact. The work is carried on by drilling and blasting two apertures, one at the top and another at the bottom of the tunnel. A squadron of workmen clears the upper aperture, standing on the diaphragm, which separates them from the lower aperture, in which another squadron of workmen is similarly employed. When these two apertures have been completed for thirty or forty yards the intervening diaphragm is blown up with dynamite, and the tunnel attains its full dimensions. It is then lined with masonry made of square blocks of stone cut from the rock excavated. About 1,200lb. of dynamite is used every day. The fragments of rock which are not needed for masonry are carried away by train and used to prepare the embankment on which the trains will mount up to the mouth of the tunnel.

St. Paul's Church, Bristol. A BAZAAR was held last week in aid of the scheme for restoring and re-seating St. Paul's Church, Portland Square, Bristol. The church was built more than one hundred years ago, and was opened for public worship on September 22nd, 1794. The pews were re-arranged about fifty years ago, but otherwise remain unaltered. Time and use have rendered the internal fittings obsolete, and they show manifest evidences of general decay. St. Paul's is regarded as probably the only church in Bristol where the worshippers are still seated in high pews with closed doors. The flooring, too, is much worn, and in some places quite decayed. It is proposed to re-floor and re-seat the whole of the nave and aisles, to remove the side galleries, re-construct the west end gallery, provide new heating apparatus, and thoroughly clean, paint, and decorate the whole of the interior of the church. The committee which has taken in hand this work are guided in their plans by the advice of Mr. G. H. Oatley, F.R.I.B.A., and estimate that about £1,400 will be spent in carrying out the scheme. In placing their case before the public, the Improvement Committee point out the marked change which has occurred in the character of the district in which the church is situated. The fine houses in Portland Square, formerly occupied by some of the best families in the City, are now, for the most part, turned into factories.

Eastbourne's New Mayor. AT a private meeting last week of the Eastbourne Town Council it was unanimously resolved to invite Alderman Strange to accept the office of Mayor of the borough during the ensuing municipal year. There are few men more widely known in the Eastbourne division of the county than Alderman Strange, who for about sixteen years has been a member of the Eastbourne Town Council. His interest in the various questions which engage the attention of the municipal administration has been reasonably comprehensive, but his speciality is sanitation and all connected with the cleanliness and health of the town. He has long held the position of Chairman of the Sanitary Committee. He was generally designated for the Mayoralty last year, but gave place on that occasion to Alderman Keay. The unanimous nomination of Alderman Strange for the Chief Magistracy this year is a happy circumstance, as his occupancy of the chair will coincide with the visit of the Congress of Public Health to Eastbourne next year, at the Aberdeen meeting of which body Alderman Strange was one of the Eastbourne representatives.



Cheltenham's Winter Garden. THE Cheltenham Town Council had a lengthy sitting last week with regard to the proposed alterations to the Winter Garden, in order to provide accommodation for social functions during the winter season, the Assembly Rooms, which for many years past were utilised, having been demolished. Plans and specifications, estimated to cost £3,500 for structural work, and heating, lighting, decoration, plants, platform, &c., to the cost of £1,950, were submitted for approval, with a resolution that application be made to the Local Government Board for sanction to borrow £5,500 to defray the cost. This gave rise to an animated discussion, in which it was argued that the building, which originally cost £26,000, should come down altogether, and the committee was roundly criticised as having been unbusinesslike. Eventually the committee's minutes were adopted.

Spring Gardens Chapel, Westminster. THE origin of Spring Gardens Chapel seems to be somewhat obscure and uncertain, says the "Daily Graphic." Spring Gardens took its name from a powerful spring of water which arose on its site, and was probably one of the feeders of the great canal now represented by the ornamental water in St. James's Park. The spring appears also to have supplied one of those fountains which were among the detestable class of practical jokes which delighted people in the seventeenth century. Examples of these fountains still exist at Chatsworth and elsewhere. They consist of a kind of concealed trap, which one treads upon unawares, starting a fountain that rises from the ground or falls from an imitation tree. Spring Gardens appears to have been partly built over about 1730, though it is not quite certain how much of it remained as a garden down even to that period. The Huguenot Chapel was destroyed by fire in 1726. The chapel was rebuilt very shortly afterwards, and used as a chapel-of-ease to St. Martin's Church. It has not been used for many years now; but it is not, as a contemporary recently stated, used as the depôt of a wine merchant. The wine merchant has his office in the vaults below, and this is probably the use to which they have been devoted from the first, as was the case with many chapels in London. Spring Gardens Chapel now belongs to the Admiralty, and with the enlargement of the new buildings of that department will no doubt disappear.

Art Galleries. MR. A. G. TEMPLE, F.S.A., the Director of the Guildhall Art Gallery, read a paper on "Art Galleries in Relation to Public Libraries" at the recent meeting of the Library Association at University College, Bristol. At the outset Mr. Temple emphasised the usefulness of one institution to the other—the help the literary student derived from a properly-organised gallery, and the material aid afforded to the art student by free access to a good library. Books, he argued, should take precedence to pictures as a public requirement, inasmuch as the uninformed mind was unable to duly appreciate the fine art of a picture. Next he pointed to the refining tendency of all art, whether it be painting or statuary; and then spoke of the galleries already established throughout the country, and of their mode of maintenance, drawing particular attention to the Walker Art Gallery at Liverpool, which he termed one of the most prosperous of the provincial galleries. An interesting feature of the paper was Mr. Temple's advocacy of the establishment of art libraries. The lecturer concluded with the practical step of naming a list of works which might form a serviceable nucleus for such a library.

Hanover Square, London. HANOVER SQUARE, W., is in a state of transformation. Not long ago it was announced that a pile of flats would be erected on the site of the old Hanover Square Concert Rooms, until recently the home of the St. George's Club, which has just been demolished; and now the famous Harewood House, which was designed by Robert Adam for the Duke of Roxburghe, has also been razed to the ground. The contents of this mansion included a magnificent collection of china and other curios, which was originally formed by Lord Harewood's elder brother, the amiable Beau Lascelles, who died in 1814. Nor is this all, for the Royal Orthopædic Hospital, which has now its headquarters at No. 15, next door, is being rebuilt in Hunter Street, Brunswick Square, so that there is every probability that this fine old building, with its curiously-painted ceilings and quaint carvings and wainscoting, will before very long be numbered with the things of the past.

A City Church Organ. RESPECTING the church of St. Lawrence Jewry, Gresham Street, E.C., a correspondent writes to the "City Press" pointing out that the old organ was built by Renatus Harris in 1687, and, instead of the contents of the instrument as now standing representing the original, the interior—that is, the actual organ—is entirely new, and was erected as lately as 1875. As regards the case, that was brought out further into the church, and the gallery supporting the organ was likewise extended and added to. The large side fronts with "towers" and gilt pipes were then also added to the main or great case. On this work the sum of about £1,600 was expended. The depth of the original main case was limited—as with all similar old organs—to about three or four feet from the front to the back, and this one extended only as far as the carved side panel.

DESIGN FOR A SUBURBAN CHURCH. By W. Lee Clarke.

STAINED GLASS.*

BY SELWYN IMAGE, M.A.

THE important, many-sided, exhaustless subject before us this evening is the relation between art and religion. I have been asked, however, in this short paper to deal specifically with a single, practical aspect of this relation, and, as far as possible, I shall confine myself rigidly to the one thing set me. I have been asked to speak to you about stained glass; and that, certainly, is a matter wholly relevant to the question we have in hand. For is there any form of religious art more popular, more prevalent, than this of stained-glass windows? . . . . Again, it is an exceedingly permanent form of art. A stained-glass window, provided violence is not done it, is practically indestructible; it is not a thing of a day, it will last for ever, and in its qualities of tone and colour will improve more and more by the action of time upon it. This being so, I need hardly labour the point that in putting up a new window we ought to have all our wits about us, taking pains to understand as far as possible the sound principles of the business to which we have set our hands, prepared for no little sacrifice in securing a thoroughly good work, and not in a hurry and fidget to have something or another set up, contented if it is at once showy and attractive. . . . . A great number of new windows, as I have said, are every year erected in the country; and, to tell the plain truth, a considerable number of these are entirely uninteresting and worthless, and had far better be out of existence.

The reason of this unfortunate state of things is that so many of the people who have the management of affairs in their hands do not understand the principles and the proper conditions of what they are about. My effort this evening, my lord, will be to try and set forth in plain words two or three of these principles and conditions, as at all events they appear to my own mind after some experience. That I have the whole secret of the matter to give you I do not for a moment pretend. That I can hope to carry you all along with me I do not for a moment dream. But I do believe that what I have to say to you has—well, has reasonableness in it, and is worth at least some candid consideration, even where at first sight it seems a little too assertive and vexatious.

What a Stained-glass Window should be.

In the first place, then, let me say this. A stained-glass window in a church ought to be, and ought to be regarded as, a piece of individual fine art, just as a picture is regarded by a genuine connoisseur, who buys it for the enrichment of his house, and will have nothing in his collection but what from the artistic point of view is worthy to be there. When the matter is put to us in this simple form few will traverse the statement; it sounds like a truism. But here, as often in things more important, it is a truism upon which we have perpetually to be returning, lest, as the poet says, "lest we forget, lest we forget." As a matter of fact, we do not find a large proportion of us, whether clerics or laymen, keenly alive to the principle we are insisting on. See how differently most of us behave in entering upon negotiations for a picture and for a window. If we think of going to the expense of an oil-painting for our dining-room we commission a good artist to paint it for us, and we do not expect to get it too readily or too cheaply. If we think of going to the expense of a stained-glass window for our church we go to a firm that turns this sort of decoration out rapidly at so much a square foot. I am not wishing for an instant to throw any stone at our stained-glass firms. Some of them are my very good friends, to whom I owe many a debt of gratitude, and their work is often most accomplished. But I know that they would be amongst the first to agree with me as to how much they are hampered by the widespread unreasonableness and ignorance of their clients. The clients force their hands both as to time and as to cost. And why? Because their clients in a considerable majority of cases do not seriously in their heart of hearts regard a stained-glass window as an important piece of quite fine art, which only a genuine artist can give them: they regard it much more on the same level as a bit of patterned stuff or wallpaper or floor covering, the design for which, once made, is endlessly produced—to be retailed at the yard for so much. We are not right, but altogether wrong, and we shall never advance a step in this matter until we recognise that a stained-glass window should be considered on the level of a fine picture, and can be produced only under the same conditions.

Three Necessary Conditions.

Three of these conditions are as follows:—First, it must be a genuine artist who designs and carries out, or sees to the carrying-out of, the window. Secondly, we must be prepared to pay handsomely for our window, as we are prepared to pay for any other first-rate professional work. Thirdly, we must have patience, and wait until the work can be matured quietly and thoroughly.

I can well imagine a natural outcry at this point, and some of my clerical friends bristling up with the objection: "Yes, it is all very well, but on these terms what chance is there of getting my church filled with glass before a blue moon?" Believe me, I quite understand the objection; I sympathise with it; it is most natural and practical. My effort to meet it brings me on to my second heading.

After all, a stained-glass window in a church is not a necessity—even from the artistic point of view it is not a necessity; it is a most desirable ornament, no doubt—something after which one should strive and make sacrifices for—but not a necessity. A window filled with plain clear glass, properly leaded into diamonds or squares, is a completely satisfactory thing. It cannot be stated too plainly, or urged too constantly, that it is far more dignified and artistic to have no decoration at all than to have decoration which is bad or paltry. I am thoroughly serious when I say that, supposing we have not the means to put wholly good decoration into our churches, we ought to regard the temptation to put up poor decoration as a temptation of the devil. Leave the place for the time being plain and unadorned; be content to decorate it little bit by little bit, gradually, as you are able; refuse to have anything there in the shape of ornament which you could not take a sound judgment upon and feel that it would be pronounced, of its kind, good. . . . As a matter of historic fact, in the old days—those days to which, so far as art is concerned, most of us look back admiringly—the builders and adorners of our churches again and again deliberately left their work unfinished, because to finish it properly at the moment was not possible; and so in faith and patience they left the completion of it to generations that should follow. One small good window in our church, a specimen of the beautiful art which those who know may look upon with unceasing satisfaction, is a far worthier thing to erect in the cause of religion, as well as in the cause of art, than twenty poor windows, for all their glamour and momentary effect of completeness. A clergyman who realises this fact and strenuously acts upon it has trouble ahead of him—that cannot be denied for a moment; but if he has reasonableness and patience he will gradually win his people round bit by bit to see the soundness of his conduct and to appreciate it; of this, too, I have not the faintest doubt. At all events, in the literal sense he is a martyr in the cause of right and truth; and the day will come, whether he see it or not, in which his wisdom and courage will tell.

New Windows in Old Buildings.

I pass to another point. In a large number of cases stained-glass windows are erected in ancient buildings—churches, for example, built in the Decorated or Perpendicular periods; and even our new churches for the most part are built more or less in imitation of some form or other of historic architecture. It is a prevalent idea that any decoration set up in these churches should be throughout in imitation of the particular style of architecture in which the building is erected; so that glass, for instance, set in a Perpendicular tracery should more or less be imitative in its manner of the glass which obtained when the Perpendicular style was in the ascendant. Now I have no hesitation in saying that I believe this idea to be a wholly false and harmful idea, and that as far as it prevails with us it stultifies our work, rendering it uninteresting and unprogressive. I believe it to be false on two grounds—on the historic ground, and on the artistic. In bygone times, when an Early English builder, let us say, came along to alter a Norman church, he did not copy the Norman work, but he frankly set about the business in his own style; or when a Perpendicular builder came along to alter an Early English church he did not copy the Early English work, but he, too, frankly set about the business in his own style; and so on everywhere, right down to this century. . . . Their work therefore had always about it at any rate this fundamental element of genuinely artistic work—namely, that it was the proper, or natural, individual expression of the feeling and thought of the people who produced it. It had in it, that is to say, the prime cardinal virtue of art: it had *style*, which is nothing else than an individual way of seeing things, and of expressing in the terms of art what is so seen.

To-day's Difficulties.

Now, of course, the difficulty which besets us of to-day—speaking of us in the whole, as an age or people—is this obvious one: that as an age or people we have no one proper, natural, individual style, in which inevitably we build and decorate. The reason of this it would take much too long here and now to try to explain, but the fact is patent and incontrovertible. But though as an age we have no distinctive style, there are plenty of good artists up and down amongst us, each of whom has a style of his own, and is a good artist precisely in virtue of his having it; and therefore, after all, we are not so utterly forsaken and badly off as at the first flush of things might be supposed. My lord, how does this bear upon the special subject of this paper—upon the art of stained-glass windows? Assuredly its bearing is obvious. If, as I said to start with, a stained-glass window ought to be, and ought to be regarded as, a piece of individual fine art, just as a picture is regarded, then when we want such a window we must go to an artist for it; that is to say, to a man with an individual way of seeing things and of expressing them, to a man with style. And when we go to him we shall say: "Give us of your best, give us something stamped with your own character and methods; here is the space that you have to fill, fill it in your own way; never mind that there is other glass in the building which other imaginations have conceived and other hands executed; fill *this* window, which is all that concerns you, with the finest work you are capable of, as the spirit moves you to fill it." In this way, and in this way alone, I venture to assert, shall we be getting into our churches the best that it is in our power to get into them; for in this way, and in this way alone, shall we be following sound principles of art, and—allowing for our altered circumstances—following, too, in the steps of those past ages whose remains so fill us with admiration.

I have purposely confined myself to but a few points suggested by my subject, but they are fundamental points, not too commonly taken heed of. That certain difficulties would arise in trying to act upon them I am far enough from denying; but, after all, that difficulties lie in the way of a particular course is no absolute reason against a man's trying to pursue it. Whatever obstacles may stand against the application of the principles I have been laying down this evening, I believe them substantially to be true and necessary principles, if we wish the art of stained glass to flourish healthily in our midst, and to avail ourselves of its best fruits. And as such I very respectfully commend them to your quiet consideration.

---

* Paper read at the Church Congress held at Newcastle-on-Tyne on September 26th, 1900.

Botusfleming Church, Cornwall, has just had a stained-glass window and memorial brass added in honour of Sir William Penn Symons. The work was executed by Mr. Taylor, of Berners Street, London.

ARCHITECTURAL ASSOCIATION.

PRESIDENTIAL ADDRESS.

By W. HOWARD SETH-SMITH, F.R.I.B.A.

THE session of this Association for 1900–1 opened last Friday evening with the annual general meeting, Mr. W. H. Seth-Smith occupying the chair. The minutes of the previous meeting having been read and confirmed, Mr. G. H. Fellowes Prynne formally moved the adoption of the report and balance-sheet of the last session. This was seconded by Mr. Elsey Smith, and adopted unanimously. On the motion of Mr. Hampden Pratt, seconded by Mr. Prynne, a vote of thanks was accorded to the honorary auditors, Messrs. W. E. Davis and E. Greenop. On the motion of Mr. Seth-Smith, a vote of thanks was passed to the Royal Institute of British Architects for its ninth annual grant of £100 to the educational work of the Association. Mr. G. H. Norman, of Old Ford, was then elected a member.

The President then presented the awards to successful winners of the Association's prizes, a list of whom was published on p. 108 of our issue for September 12th. Mr. Seth-Smith then delivered his presidential address, of which the following is a *résumé*:—My first word must be one of congratulation upon the

Prosperous Condition

of every department of our Association. We now number 1,291 members, and no one taking the trouble to read the annual report can fail to observe how great and varied is our work, how well it has been maintained, and how rapidly developed. There has been uninterrupted progress in the growth of our membership from the first. That prosperity during the past two years has beenin no small degree due to the enthusiasm and unwearying exertions of the retiring President, Mr. George H. Fellowes Prynne (ably assisted by the energetic Committee and other officers). His admirable epitome of the history of our educational work in the past, as given in his first presidential address, relieves me of that difficult task. His devotion forms a record surely even in the Architectural Association, to serve which nearly every well-known London architect, and many in the provinces, have cheerfully given so much time, thought, and experience. I hope the Association may before long be in a position to realise his workshop scheme. It is only want of space which has so far hampered what our students much need in this direction.

It is my duty to record our sense of loss in the death of six of our members during the past session. On the whole the students have shown commendable zeal by supporting all branches of our work, but it is necessary to warn some that no reading at home will make up for irregular attendance at the studio and the classes. System is as essential to study as to practice, and must be adhered to if we are to become proficient. Our Registrar reports that when business is brisk in London he has no difficulty in finding a good berth for every well-equipped young man when he emerges from the student stage; but the register contains too many who lack a knowledge of construction or the ability to design, and who realise too late their neglect of precious opportunities for making themselves competent assistants, and, in due course of time, capable architects. On the other hand, I would advise those working in the classes not to slacken their home work or to relax their exertions as the session advances; some students commence with enthusiasm, but as the session progresses their earnestness appears to decrease.

Our School of Design

offers the greatest attraction and the most unique opportunity for cultivating skill and taste. The subjects, as you know, are set and the designs are criticised by a large number of the most artistic and able architects in London; nor can I refrain from urging our students never to miss the spring or summer visits, by which we arrange to see the best old work as well as the most important buildings in progress of erection. Can anything be of greater value to all of us, old or young? The power of giving public expression to our thoughts and so of eliciting the ideas of other men is one to be cultivated by every young man, and members will find a fitting opportunity for this side of their education in our Discussion Section. They will at the same time be surprised at the amount of knowledge they derive from the debates. I scarcely think our A.A. Sketch Book, in which the best measured work of the members is published in quarterly parts, and which makes such a valuable book of reference in any architect's library, is sufficiently well known. We shall be glad if some of the members are disposed to encourage the energetic honorary editors, Messrs. W. A. Pite and W. G. B. Lewis, by subscribing to it this year. The library needs better support. Students should not be afraid of borrowing certain books on account of their large size.

Perhaps many of our young men are too busy in their evenings to attend more frequently than they do the papers read to us by the best men on the various subjects selected. Let me say they little realise their loss every time one is missed. Such papers generally represent the experience of a lifetime compressed into an hour's discourse and given gratis. The generous way in which these Esaus part with their birthright to their hungry younger brethren often astonishes me.

Gentlemen, we are entering upon the session which will see the commencement of

The Twentieth Century.

It is the privilege only of a very small minority of mankind to experience the emotions which such an occasion must inspire. To a much smaller number has it been given to review a century such as that to which we bid farewell. Shall we be safe in defining true progress as the increase of the sum of human comfort and happiness? If so, surely the past century has seen more progress not only than any previous hundred years, but perhaps than all previous centuries put together. The root of this progress has been the practical application of the central truth of Christianity—namely, the universal brotherhood of mankind—and from this root has sprung universal education, and to education may be attributed all the splendid achievements of modern science. But amid this phenomenal activity in science, has art been asleep? or has she made any corresponding contribution to human happiness? Has it been a century as fertile in the production of poetry, painting, sculpture, and architecture as in the discoveries and inventions of science? Perhaps not. This is an interesting inquiry, and my own belief is that the intellectual activity of the century has shown its influence in art, as well as in science, though not in the same degree. A century which has produced the great and essentially English water-colour school and such truly poetic schools as are best represented by Corot and Millet in France, and by some perhaps equally great Dutch and English artists, notably Turner, cannot be said to have been indifferent to art. Poetry and architecture, too, have been active enough in all conscience, even if wanting in concentration and consequent power. Music may be said to have triumphed; we are fast becoming a musical people.

Science and Art.

The faculties and habits of mind which respectively develop science and create art are essentially different; the one class of mind is objective, the other subjective. The one is inquisitive, familiar and practical in her friendship with Nature, the other is reverent and imaginative. The two classes of mind, both Nature's offspring and complements of one another, may be living their own lives side by side in an age in which the mind of the vast majority of men is centred upon science and its material benefits, but that age is in the nature of things unlikely equally to encourage, though it may pave the way for, the fine arts. Do not misunderstand me here, art is not a rival of science but it is a higher law regulating, and a feeling pervading every invention. We are on different ground, however, directly we deal with the applied art of architecture. Here we shall find that science has always been the origin of its greatest departures. The arch and its multiform developments and resultant features are ancient witnesses to this truth. If we consider, moreover, the extent to which education and sanitary science have multiplied and specialised the buildings which we are now called upon to design, we shall recognise at once how enlarged are our functions, and how likely it is that the twentieth century will see still greater developments. As regards

Monumental Architecture,

the imperious command of one great patron has given place to the more imperious directions of a co-operative body themselves merely fiduciaries of the will and purse of the community. But the wants of this co-operative community, if not so colossal, are infinitely more numerous and varied. They call for town halls, municipal offices, colleges, schools, polytechnics, hospitals, asylums, workhouses, electric lighting stations, baths and washhouses, &c. Surely, gentlemen, there is no room for disquietude as to the future of architectural practice if our training is equal to the demands of the public and if the policy of our profession is broad and well directed. All these are modern requirements, and show how really changed are the conditions of our work, how varied and how complicated that work has become, and how impossible it is to put the hand of time back, or to depreciate the influence of science. Why should we struggle to cast the mould of future architecture to the form of our own narrow and short-sighted prejudices? Our duty is clear and unmistakable—namely, to accept, and to accept joyfully, the altered conditions of our age and to do what our hand findeth to do in a spirit of devotion to the present and confidence in the future.

Taking its origin in the knowledge of building construction, and inseparable from it, the essence of architecture is nevertheless

Beautiful Design,

design full of thought and feeling. This differentiates it entirely from mere construction, however rude or however scientific. This constitutes our art. Design is to building what religion is to life, what poetry is to language—the indefinable and spiritual, the changeless element, the one thing needful. It leaves the prose and business of our calling essentially what they were, every department of our buildings worthy of our close and vigilant care, but makes us conscious of a higher order of desire and affection that guides us through all these and lifts us above commercialism. The latter is the instinctive faculty common to all, the former (art) is the conscience. The man who has this spirit is alone the true architect, and the ideal society of architects would be one from which all others would be excluded. It is the decree of providence, however, that both shall grow together, in spite of our rough tests, which may, it is true, do much, but can never be infallible. We need not regard engineers or builders as serious rivals in our field so long as we are true to this ideal and insist as far as practicable on its possession and its cultivation by every man who bears the title of architect.

Allow me to utter a note of warning to our students against pinning their faith exclusively to any of those schools of thought which lack the sense of proportion and tend just now to lead us away from the broader fields of systematic study, schools which on the one side insist that we should be content to be craftsmen and builders, and on the other hand appear to regard draughtsmanship and design as the be-all and end-all of an architect's training. None can know too much of construction, none can draw too well, but bear in mind Sir Joshua Reynolds' remark: "How difficult it is for the artist who possesses this facility (of accurate and rigid declination) to guard against carelessness and commonplace invention is well known." How frequently we see this truth illustrated in Royal Academy pictures by the cleverest men. Then there is the

Non-traditional School

insisting that we should divest our minds of the forms of past work and invent our own. All these schools have originated in the gross neglect of training in draughtsmanship in some, the equally egregious want of practical knowledge or a slavish copying of ancient architecture in others. They are each emphasising all important truths, and wherever great truths are enunciated, be they only a fraction

of *the* VERITIES, we should receive them gladly. As a matter of experience it will be found that the full truth lies somewhere between these extremes, and that the best architect will be both a wise and experienced builder and a good draughtsman and designer. If he be great enough to add archæology and other subjects he may be a happier man but not necessarily a better architect.

It is not to be expected that many men should be equally strong on the scientific and artistic sides of our calling, nevertheless there is no excuse for the existence of two classes of architects which specially bring the profession into disrepute, on the one hand those who are grossly ignorant of structural work and confine themselves to the study of design from the artistic standpoint, and on the other hand the men who have technical knowledge but who ignore architecture as an art. It is difficult to say which of these classes does the most harm.

The keynote of the best work of our younger men is enthusiastic love of beauty in form and colour (irrespective of the amount of remuneration its pursuit may bring), thought as to the capacities of the material in hand, and individuality in feeling. It is fearful of the pedantic and the commonplace, faults so often associated with too academic a training. Can we wish for a better spirit? Personally I have no fear of the future of English architecture on the score of pedantry. Our lithic language savours perhaps *too* broadly of our national characteristic, individual freedom. We are apt to forget how much our literature and even our fine arts owe to exotic sources. We can surely afford to be as tolerant professionally as we are nationally and imperially.

The antidote of academic uniformity lies in the

Study of Nature.

The man who keeps his mind in harmony with Nature will have recorded, however unconsciously, the great principles underlying stability and composition everywhere observable in Nature. These principles, violated as they so often are in our buildings, will be instinctively detected and condemned by a true artist, to whatever branch of art he may belong. An architect imbued with these principles will not advise his clients to erect a severely classic style of house in a very rural spot. He will select a more picturesque type as more harmonious with its surroundings. It is the withdrawal of all Nature's conditions and restrictions which makes a more formal and dignified style more suitable to city architecture. Of course if your building approaches the scale of a palace and the interval between it and unfettered Nature can be disciplined by formal and architectural gardens it is another thing. So far our sense of fitness has been so true that English country houses are renowned for their appropriateness to their environment. It is this contact with Nature, moreover, which, with her infinite variety appealing to the equally diverse character of the human mind, will preserve our individuality of taste. I submit that it is the neglect of this study in France which has done so much harm to its rural architecture. The French architectural school is one of exclusively civic and monumental artists. It is at home among man's creations, it appears to have no sympathy with the works of Nature.

On the other hand, Mr. Warren in his paper read before the last annual convention of the American Institute of Architects, on the influence of the French school of design upon architecture in America, most justly commends this school for its insistence on composition, its excellence of proportion and mass, and its mastery of monumental planning. These points are admirably exemplified in the two new palaces in the Champs Elysées, and we shall do well to study them carefully.

A notable feature of our people has always been to preserve a

National Character

in all our institutions and in all our schools of art, while freely adopting such features of other systems as commended themselves to us. It has always been so with our architecture; it is so to-day; and this consideration warrants confidence that our architectural profession will not blindly follow any school, but evolve one of our own.

It is upon a wide basis that the A.A. curriculum has been founded and has worked so well. The better education of the profession is our mission. It is a mission which finds support and sympathy from every school of thought among us, and it may be safely said the A.A. has not an enemy, scarcely a critic. Our watchword has been, and will I hope ever be, *continuity of policy and progress with the times.* How are we fulfilling our mission? Our educational work is, as you know, conducted wholly in the evening, there are 200 students attending our courses, and about 200 more of our members may be said to be still in the student stage of their career.

The characteristic of our Architectural Association seems to be, to use the pithy expression of a popular past-President, *the power to enthuse.* But enthusiasm, like others among the best of of things, is a dangerous endowment unless well directed; it has led many a man to be impatient of that strenuous effort for the mastery of the prose of building which is so essential, but this patient and sometimes irksome work will alone give him a solid satisfaction, without which enthusiasm for art must wither and die in the failure of his practice. As to the need for the study of the history of design—a point much debated just now—I venture to reiterate the words of the reader of an able paper two sessions ago. Mr. Reginald Blomfield then said what I believe to be profoundly true, and I quote him because we all regard him as a good architect and because I cannot put the thought into better language: "In architecture, the oldest of the arts, we can only consider ourselves on safe ground so long as we keep in touch with what has actually been. The days of the craftsman working independently, yet in unconscious unison, ceased when the choice of styles arose. He tasted of the tree of knowledge, and henceforth to his knowledge of the craft had to be added the responsibility of conscious judgment if he were to undertake—I will not say architecture, as it might be thought to beg the question, but building of any sort. Because, in any building nowadays, a man has to use one method of expression in preference to another, and implicitly in this there is raised the whole question of selection. Now this responsibility proved too much for the simple craftsman, as you may see from the blunders in design which abound in more ambitious Jacobean works; and it was only a question of time how soon there should arise the man who had sufficient training and intellectual capacity to enable him to discriminate between good and bad, to enable him to grasp the

Logical Coherence in Expression

which is an essential element of architecture. As soon as such a man arose, the matter was settled for good or bad. The architect ceased to be a craftsman in the technical sense, and what might be lost in craftsmanship was assuredly gained in architecture. I think therefore that this critical function of an architect, this detachment from the actual details of craftsmanship which chafes the enthusiasm of some of by no means the least gifted of our younger men, is of the very essence of his work. His craftsmanship must be of a wider range; it must embrace full knowledge of the past; it must rest on a constant habit of analysis of the best methods of expression in building."

One thing on which all who are experienced in the training of the human mind are agreed is that a good *general* education must precede special knowledge. This is an axiom which guides your committee in their educational work. It finds expression in the large number of subjects we provide, all of which we consider important every architect should be acquainted with. It is essential that our curriculum should aim to be comprehensive, to lay a good foundation of general architectural education which will fit men to adapt themselves as readily as possible to the special line they may wish, or be compelled to adopt. If your foundation is not sufficiently deep and wide, you will sooner or later show signs of settlement.

So much for our successful past and hopeful present. I will now with your kind indulgence deal with what I am persuaded we ought at once to take in hand. I refer to the establishment of

Day Courses

of instruction, and I will give you reasons, which I think will commend themselves to you as indisputable. Not that I claim originality for this idea. It has, like almost every other subject which affects the profession, been discussed many times by your committee, but dismissed for the time being mainly on financial grounds.

In the first place, our system of pupilage, necessary and excellent as it is in principle, is still admittedly and radically faulty from the standpoint both of the master and of the apprentice. The former is too busy to undertake the pupil's education; it is as much as he can do to give him the run of his office, to allow him to spoil material and waste his paid assistants' time in gleaning what information he can. The latter finds himself irrevocably bound to serve at least three years, even if he discovers within the first few months that he has mistaken his vocation. A two years' full course of study in a *purely architectural college controlled entirely by experienced architects* would obviate both these objections to the present system without in the least endangering it, and I am sure that most architects in practice, and probably every Fellow of the R.I.B.A. would, as an encouragement to a movement which would secure useful servants from the first, not only agree to accept a rather smaller premium, but probably also to a lengthy apprenticeship. The pupil, on the other hand, would as a rule discover during his first two or three terms in such a school whether he were fitted for the work, and would be free to drop its further pursuit without loss of time or premium. It would be a truly advantageous arrangement to both parties.

New Premises.

Another cogent reason is that we already have the premises needed for a start, most of the apparatus and some of the staff, and that consequently we can run the school economically, and in about three years' time it ought to become a substantial source of revenue, enabling us to do what we have of late proved we cannot do on our present income—viz. build or rent premises to suit our ever-growing needs and in a neighbourhood worthy of our position. If we fail to seize this opportunity, others will certainly do the work which I believe to be the great mission of this Association. With the exception of the Victoria University at Liverpool King's College is, I believe, the only institution in this country which has an architectural day school, but King's College architectural course appears to be a department of what is really an engineering school. We should have no difficulty, I am sure, in obtaining guarantees of financial support for three or four years, during which we must expect to make a loss. This was the method pursued so successfully in 1891 in launching the present curriculum.

Our standard of training is far behind that of other countries. The paragraph in Messrs. Florence and Balfour's report of the drawings exhibited at the Paris Exhibition is not flattering to our English pride. It reads thus: "Your delegates could not help comparing the skilled design, the able execution, the artistic feeling and patient care displayed in these drawings, with the careless and slap-dash effects which seem to be sufficient for the student of the present day in England."

[The president here referred to and quoted at length Mr. Arthur Cates' article, in the June number of the "R.I.B.A. Journal," on "Architectural Education in the United States of America."]

Let the Architectural Association hope for some liberal benefaction to put the systematic professional

University Education

on a satisfactory and permanent footing. There are many very wealthy men in this country who sufficiently realise the immense importance of the art of architecture as the most important and permanent expression of civilisation and of national greatness to con-

tribute in a substantial manner to the establishment of a College for the education of the profession, if once they became aware of the urgency of the need. It is not generally realised how poorly paid the architectural profession is, and how, consequently, impossible it is adequately to endow its own teaching. A school such as I suggest this Association should open would be a fair start for the high training we so much need. It has probably occurred to many that the Association, as the principal architectural teaching body, should be officially recognised by the new London University. The committee will not lose sight of this important question, but, in view of the character and standard of technical training the University requires, I do not think we can just now expect to do more than obtain its official recognition for our teaching staff.

As Regards Examinations

the good old English proverb is true to human nature, "You cannot put an old head on young shoulders," and no man of common-sense expects more than a very small fraction of youths to be sufficiently enthusiastic (in the abstract) to put forth their best efforts to acquire skill and knowledge (for their own sake) before they know their joys and their value as a means of livelihood. It is therefore necessary to provide some incentive to work. Our system of studentship and of prizes is founded, of course, on this obvious truth. Experience proves that the best course of systematic training falls to the ground without some such stimulus. There is no prize so precious as the testimony of the leaders of one's profession that one has sought by long and well-directed study to make oneself proficient in one's calling.

I find that out of the total number of London candidates in the R.I.B.A. qualifying examination last year, 48 per cent. in the intermediate and 63 per cent. in the final were students of this Association. The possession of ability to design and to draw are comparatively rare gifts (in combination especially with business and constructive capacity), but they are absolutely necessary to an architect. Both can be sufficiently tested to exclude from the Institute men who are grossly deficient in these qualities. Can anything therefore contribute so greatly to the improvement of architecture, as an art, as an examination in these? Let it be borne in mind that the temptations to take up architecture as a business are as numerous as the opportunities are great as compared with those presented by painting or sculpture. Consequently we are bound to choose between retaining our present examinations in art (as well as science) as a qualification for membership of the Institute or of admitting builders equally with architects to a test of knowledge of construction *only*, with the certainty that this qualification would in the public estimation be equivalent to a complete architectural equipment. This *art* test is our only hope of purging the profession, as far as may be, from the commercial spirit, the

Worship of Mammon.

In the words of Louis Stevenson: "If you adopt an art to be your trade, weed your mind at the outset of all desire of money. What you may decently expect, if you have some talent and much industry, is such an income as a clerk will earn with a tenth or perhaps a twentieth of your nervous output. Nor have you the right to look for more; in the wages of the life, not in the wages of the trade, lies your reward; the work is here the wages."

On the still larger question of the legal protection of the title of architect I would call attention to the growing feeling abroad, as represented by the resolution by Monsieur Couran—carried, I understand, with unanimity—at the recent International Congress of Architects at Paris. It runs as follows: "That governments take measures to protect and ensure respect for the title of 'architect' by reserving it for the future, and without retroactive effect, to architects provided with a proper certificate, by forbidding others to use it, and by putting it within the reach of all by means of the diffusion of architectural education." The prospects before us were never so bright as to-day. Besides the ever-growing demands at home for all kinds of special public buildings, there lie beyond our shores immense and rapidly ripening fields for architectural skill. Few of our young men can have considered the growth of innumerable towns in Africa, India, and the more Eastern of our colonies, without its arousing the spirit of adventure and a certainty of occupation; and bear in mind that it is London-trained men who are mostly in demand for such situations.

When cities are being conceived and largely erected in two or three years (Khartoum, for instance), all designed by Royal Engineers, one asks oneself, What training in architecture do Woolwich and Coopers Hill and other colleges afford? I believe, *nil*! If art is not for ever to be ignored by English Governments, why should it not be made a rule that each young engineer who is appointed to government architectural work in the great cities of our dependencies should have a year in our leading architectural schools or offices?

A movement among us full of promise for the future of architecture, and one which was the key-note of this year's Congress of Architects convened by the Institute, is the alliance of the architect, sculptor, and painter as well as the artist-craftsman in the production of a building of any importance. Such brotherly counsel, combined with a clear conception in the mind of the architect of the effect required, ought to result in buildings of greatly increased beauty and interest. It would tend to this happy co-operation in the constructive and decorative arts if our studio could in some way be made preparatory to the Royal Academy School of Architecture, which naturally will take only advanced students. If this were found impracticable, possibly on the social side of the A.A. (a side we hope will ever be encouraged by all concerned) a rendezvous may be devised which will bring the students of all these arts into closer touch in their early days.

What age other than our own can claim to have supplied subjects for sculptors and artists so magnificent in their conception or fraught with greater hope for the immediate benefit of mankind in general? They may record in stone and colour in our buildings the vast truths of evolution, or celebrate the welding together of an empire whose arms exist alone for the defence of liberty. Can we as architects have a higher ideal before us than to dignify and beautify the Metropolis of such an empire? And this should be the ambition of every member of our Association; and then, when it is done,

"We shall rest, and—faith! we shall need it—lie down for an æon or two,
Till the Master of All Good Workmen shall put us to work anew!
And only the Master shall praise us, and only the Master shall blame;
And no one shall work for money, and no one shall work for fame,
But each for the joy of the working; and each, in his separate star,
Shall draw the Thing as he sees It for the God of Things as They are!"

DISCUSSION.

Mr. G. H. Fellowes Prynne, in proposing a vote of thanks to the President for his address, said he thought the falling-off in the attendance of students at the end of the session was due to the attempt to rush too quickly into the advanced class of design, where the students got discouraged. He thought they should be forced to go through the elementary class first. He thought the President should have mentioned with the other artists of the century Sir Edward Burne-Jones and Alfred Stevens. Architects at the beginning of the century ignored iron, but engineers had at once grasped its advantages, and their works were monuments to science. He could not agree with the suggestion that engineers should pass one year in architectural training, as he thought they would then think they knew all about architecture. What was wanted was combination of the architect and engineer. It would be an excellent thing if day-classes were started; but he was afraid, if the financial support had to come from architects, these classes would be a failure. They ought, however, to be able to find someone interested enough in their art to give financial aid, as had been done to other institutions. He sincerely hoped we should see the college system for architects.

Mr. E. W. Mountford, in seconding the vote, thought the falling-off in attendance at classes was due to students feeling they required a little recreation.—Mr. C. H. Strange drew attention to the merits of the Discussion Section of the Association.—The vote was then carried by acclamation, and in reply Mr. Seth-Smith said that with regard to Mr. Prynne's remarks upon the success of day-classes he had made careful calculations, and he did not think there would be a loss of more than £1,000. Towards this sum several of his friends had given promises of help to the extent of £500.

Surveying and Sanitary Notes.

New Members of the Institute of Sanitary Engineers.—At an examination in practical sanitary science held on September 21st and 22nd T. R. Atkinson, Penrith, passed qualifying for membership, and the following qualifying for associateship: J. Jenkins, Harlow; and H. J. Hammick, Stonehouse, Plymouth.

The Preservation of Hampstead Heath.—The annual report of the Hampstead Heath Protection Society records that through the instrumentality of the society a resident superintendent ranger has been appointed for Golder's Hill, Hampstead Heath and Parliament Hill Fields. Other matters on which influence has been brought to bear are the damage done to shrubs, &c., by the sheep which are allowed to graze on the Heath, the fencing-in of areas from which vegetation has disappeared, the shooting of cinders on the Heath, and the over-planting of trees, &c.

The Western Counties Cement and Flag Making Company have recently established new works in the Ormsgill district, Barrow. Mr. T. Oddy, the manager, has had the sole charge of the designing and laying-out of the whole of the works, buildings, engines, boilers, machinery and shafting. The engine-house is lofty, and gives plenty of light. The engines, of 300 h.p., are compound condensing with a belt fly-wheel 11ft. in diameter and 2ft. 6in. broad, weighing 11 tons. The engine-house stands in the middle of its own water reservoir, the basement of the engine-house wall on two sides forming the sides of the water tanks. These tanks are connected with extensive cooling culverts, 6ft. high and 3ft. broad, running through the base of the engine-house and to the extreme limits of the land on each side. The American grinders are fed from a massive wooden hopper in the room above, which holds two large railway trucks of prepared cement at one time. These two machines are each supposed to turn out five tons of finished cement per hour. The cement is fed, ground, elevated, and sacked, without being touched by hand, seven sacks being filled at one time. The slag dryer, a revolving cylinder 40ft. long, slowly revolves and keeps turning over and propelling the slag and drying it by a very hot furnace underneath, the heat from which is drawn through the slag and cylinder by a hot-air fan driven at high speed. This dryer will turn out five tons of slag per hour. The flag-making department has an ingenious flag-making machine which turns out a flag 3ft. by 2ft. 6in. by 2ft. in three minutes, and ready edged. The machine is so arranged that four moulds are in process of being filled, pressed and stamped at the same time. The pressure exerted by the hydraulic ram is 2,500 tons, or 2½ tons per square inch.

A New Fountain at New Brompton has been erected at the corner of the Lines, near the Post Office, from money collected at last year's "Carnival." The fountain is in salt-glazed Doulton ware, 8ft. in height. The base is square, the lower part relieved only by an inscription, which is repeated on opposite faces of the fountain. At the level of the basins the design becomes more ornamental, and each face is set back in the form of a niche filled with ornament and finished by a semicircular "shell-head." This portion ends in four curved pediments, from the central intersection of which rises a finial.

Law Cases.

Letting Uncertificated Houses.—At Birkenhead recently William Davies, of 27 Albert Road, was summoned for unlawfully letting seven dwelling-houses in Connaught Street without having been certified by the Borough Surveyor. It appeared that on June 29th Mr. Warwick, Corporation Inspector, inspected the houses, and found they were tenanted. On a further examination he found they were incomplete, for the drains were unable to stand the smoke test. They were all in a similar condition. In defence defendant said he had not capital enough to finish the houses. A fine of 10s. and costs in each case was imposed.

Adding a Storey without Authority.—A short time ago Emanuel Ellis, builder, Heswall, was summoned at the Neston Petty Sessions for contravening the by-laws of the Wirral Rural District Council. Mr. W. H. Mathison, who prosecuted, said there were three summonses against defendant for not submitting complete plans of a house he had erected in Liverpool Road, Heswall; not providing sufficient airspace in the yard at the back; and not making the external and party walls of the thickness required. Defendant had erected a three-storey cottage, and the space at the top he had made into bedrooms not shown on the plans. As the house was now of four storeys, the walls ought to have been thicker. A fine of £1 and costs in each case was imposed.

The Laying of Drains. — Thomas Kyne, builder, was recently summoned at the Sheffield Police Court for failing to specify the lines of drainage on plans submitted in respect to four houses he was building in Penistone Road, Sheffield. On October 28th last year the defendant sent in plans for the houses. The plans were passed; but when, on June 23rd, a Corporation inspector went to examine the drains, he found that the defendant had provided an entirely different system of drainage to that previously approved. It appeared that previous to the latter date the defendant had sent in an amended plan, but this was rejected. He nevertheless proceeded with the work. The Chairman said the defendant must take the consequences of having deliberately disobeyed the authorities. He would be fined £3 and costs.

Mortar Without Lime: Fine Imposed.—At the Sheffield Police Court recently Mr. T. H. Johnson, surveyor and builder, Priory Place, Doncaster, was summoned for using defective mortar in building some houses in Chippingham Street and Titterton Street, Attercliffe. The evidence of several building inspectors who had examined the work was that mortar which had been used over an area of about 150yds. was deficient in lime, and therefore useless. Mr. Neal, for the defence, admitted that inferior mortar had been used over a small part of the building, but said that the defendant was ready to remedy what was complained of. Mr. Johnson was away at the time, and in his absence his foreman had used the mortar without lime. He had built a large number of houses in Attercliffe without previous complaint. Mr. Johnson gave evidence in support of this statement. A fine of 40s. and costs was imposed.

The Art of Bricklaying.—At the Spelthorne Petty Sessions, held at Sunbury, Messrs. Lock Brothers, builders, of Ashford Common, were recently summoned by Herbert Blanchard to settle a dispute with reference to the terms of his apprenticeship. Complainant's case was that the defendants did not carry out their engagement, as they had not taught him the trade of a bricklayer, but had simply given him menial labourer's work to do. He had given the firm £14, and as they had broken their agreement he asked that some or all of this amount should be returned to him. In evidence he said that he was put to any work that came to hand, and only occasionally was he engaged in bricklaying. He had scarcely been taught sufficiently to build a wall. He did not say that he was not given bricklayer's work when there was any to do, but the firm had not sufficient work to teach the trade. The defence was that the art of bricklaying was not confined to the actual laying of bricks, as the complainant seemed to think. In answer to questions the complainant said he could build from foundations, and he could manage corners, but not much else. He did not expect to learn all the trade in two years, but he was not satisfied with what he had learnt. At the present rate he did not think he would learn the trade in five years, the length of time he had agreed to serve. He did not complain of his wages—17s. per week. A skilled bricklayer could earn 10½d. per hour, and at present witness could only earn 6d. per hour, the labourer's wage being 5½d. It was suggested for the defence that the reason the case was before the Court was not because the complainant had not been taught enough, but that he had been taught too much, for, finding that he could earn a larger wage outside, he was anxious to break his contract. There was nothing in the trade that the defendants were not ready and willing to teach the man. The Bench held that the indentures had not been broken, and dismissed the summons.

New Patents.

These patents are open to opposition until November 12th.

1899.—Artificial Granite.—17,966. R. Haddin, 18 Buckingham Street, Strand, W.C. (communicated by La Société Berthe et Cie., Paris). "Granatine" is the name given to the material made according to this invention. It consists essentially of cement-mortar to which different pulverised materials are added, particularly glass waste. The manufacture is entirely done in a cold state, and the resulting substance can be easily polished when it has set. (This takes a few days.)

Artificial Sandstone.—18,058. H. C. Meurer and F. T. Bormann-Zix; both of Stadelhoferstrasse 40, Zurich, Switzerland. The blocks are made of a hot and homogeneous mixture of sand and a saturated solution of pure hydrate of lime, and can be subjected, without any need for previously treating or protecting them, to the direct action of high-pressure steam for the purpose of hardening them.

Artificial Marble.—20,347. H. A. Pryor, 70 Chancery Lane, W.C. (communicated by J. E. Summers, Lynchburg, U.S.A.). This invention obviates the necessity for polishing and graining artificial marble, and it consists in mixing together lime water and silicate of soda, then adding Parian or similar cement in sufficient quantity, and finally adding pigments. The mass is then allowed to harden on a very smooth and polished surface.

1900. Pots for Paints, Stains, &c.—8,731. E. G. Hill, Holloway Street, Minehead, Somerset. The can tapers slightly upwards, and has a hinged lid and a clip on the inside of the body-part for holding a brush. The object of the invention is to do away with bottles with holes in their corks (as used by French-polishers) and similar trade appliances.

The following specifications were published on Saturday last, and are open to opposition until November 19th. A summary of the more important of them will be given next week. The name in italics within parentheses is that of a communicator of an invention.

1899.—12,760, Baker, brackets for supporting curtain poles, &c. 18,061, Scott-Moncrieff, bacterial purification of sewage. 18,442, Stanley, manufacture of bricks, tiles, &c. 19,868, Hill, apparatus for checking workmen's time. 19,860, Brady and Rittenhouse, street-sweeping machines. 19,902, Fleming, reservoir brush, especially applicable for spreading gum, paste, &c. 20,132, Flooks, apparatus for making mortices and slots in doors. 20,438, Barker, means for holding shades or globes for electric and other lights. 20,473, Allison (*Hubbard*), hot-water heaters. 20,681, Williams, container for automatically distributing liquids to flushing cisterns. 21,336, Hilton, metallic lathing. 22,413, Neville and Carpenter, means for preventing downdraught in chimneys, &c. 22,563, Alliott, filter presses. 22,655, Hall and Hall, self-acting loading and unloading hoists. 22,993, Cooper, tramway rails. 23,293, British Thomson-Houston Co., Ltd., and Samuelson, trolley stands for electric railways. 23,774, Joseph Place and Sons, Ltd., and Place, chequer brick for kiln bottoms. 23,995, Darby and Darby, baths. 24,459, Spong, self-igniting gas appliances. 25,138, Dorman, acetylene gas generators.

1900.—2, Enright, fastener for gates and doors. 4,745, Turner, apparatus for cleaning out pipes and tubes. 12,915, Sheppard, manufacture of glass. 13,052, Prüss, construction of partitions, walls, &c. 13,129, Jaeger, machines for moulding bricks. 14,320, Letcher, gas blow-pipes.

SHEFFIELD BUILDING TRADES' EXCHANGE.

THE erection of this exchange for the use of the master builders of Sheffield and their clients will be commenced this month, the necessary land having been purchased from the Corporation at the corner of Upper Charles Street and Cross Burgess Street. A small limited company, with a capital of £6,000, was formed a short time ago to carry out this work. The idea of the promoters is to provide a building which shall be used on Tuesdays as an exchange, where the local builders can meet and transact business with the numerous travellers of the stone, timber, hardware, iron construction merchants and others with whom they have dealings; as a sort of club throughout the week; and as the home of the Sheffield Master Builders' Association—now a large and powerful organisation. The entrance to the exchange will be in Cross Burgess Street, and lead direct into the large room to be devoted to the transaction of business. Under this room, abutting on Charles Street, several shops are to be built. The apartments include offices, billiard room, committee room, cooking kitchen, and three bedrooms for caretaker. A special feature will be the provision of all the trade journals, literature, and works of reference which are useful to members; and refreshments, including luncheons and teas, will be obtainable. The plans have been prepared by Messrs. Gibbs and Flockton.

Professional Practice.

Bootle.—The new Municipal School, which was opened recently, occupies an open site at the corner of Balliol Road and Pembroke Road, the principal frontage looking on to the former thoroughfare. Mr. Corkhill, of Liverpool, is the builder, and the cost has been about £20,000. The architects are Messrs. Best and Callon. The new school is grouped round a large quadrangular court, which is divided into two on the ground floor by the assembly hall, this, together with the workshops, enclosing the back of the quadrangle, being one storey only in height. The front and sides of the quadrangle are two storeys in height. Ground Floor:—The entrance is central in the main front to Balliol Road, and leads into a hall, round which are grouped the administrative offices, and from which lead the main corridors serving the whole school. The assembly hall for lecture and examination purposes is directly opposite the entrance. The west wing is occupied by the women's manual training department. The east wing, in addition to three ordinary class-rooms for thirty, forty, and thirty-six students respectively, contains the physical department. The latter consists of a laboratory accommodating about forty students, and lecture theatre for the same number, with preparation and dark room. The workshops occupy the north side, and include a carpenter's shop for twenty-seven students, a metal-working shop for thirty students, and a plumber's shop for thirty students, all being approached by a special corridor. A heating chamber is provided in the basement. First Floor:—Two wide stone staircases in the front or main corridor lead from the ground to the first floor. The main front in Balliol Road is

occupied by the Art School, and contains elementary and advanced rooms, modelling room, library or spare class-room, and art master's room. These rooms have large north lights arranged according to their requirements. The west wing is devoted to the chemical department, separated by a well-ventilated corridor shut off by swing doors. It consists of a laboratory accommodating thirty students, with balance-room attached, lecture theatre for forty students, and a preparation-room in direct communication with both theatre and laboratory. It may be noted, as an improvement upon the usual system, that in the laboratory short benches only are used, accommodating four students each. The east wing contains three class-rooms, accommodating respectively thirty, forty-two, and forty-eight students, and a large engineering drawing class-room for forty students. The heating of the school is effected with low-pressure hot water, with radiators constructed to supply warmed fresh air to the rooms. The ventilation is by mechanically admitting fresh air to the rooms through radiators and wall inlets. The vitiated air is extracted at the ceiling level, and is conveyed along ducts to the main upcast shafts, in which are fitted large electric exhaust fans. The building is lighted throughout with electric light, the installation having been effected by Messrs. Brook, Hirst & Co., of Chester. The main idea in the treatment of the exterior has been to produce a building suitable to the purposes for which it is used, and as simple in form and design as a public building of this size and character can be. The elevations are treated in a free classic style of Georgian type, and are executed in Ruabon and red bricks, with Knowsley stone dressings, the roof being covered with Westmoreland green slates. Four schools are to be accommodated in the building. First, the evening school, consisting of many science and commercial classes, and some trade or technological classes; second, a school of art, located in the upper rooms on the Balliol Road frontage; third, a school of domestic economy, placed in a special portion of the west wing; fourth, a day school for boys of twelve years of age and upwards. Messrs. Sloan and Lloyd-Barnes have acted as consulting engineers to the committee, in regard to the engineering workshop.

Burton-on-Trent.—The Primitive Methodist Chapel in Welmore Road is about to be enlarged and altered. The chapel will be increased in length, and at the back a new block of class-rooms, with vestry, copper-house, and lavatory accommodation for the schools, will be provided. The front will be entirely remodelled, and will have a new entrance porch with a large four-light window above and two two-light windows on either side. The walls to be faced with best red bricks, having window dressings, gable and coping of stone. The architect for the work is Mr. Thomas Jenkins, of 35 High Street, Burton-on-Trent.

Hull.—The Corporation of Hull, having determined upon extensive street improvements involving the clearing away of slum property, are commencing the erection of three blocks of working-class dwellings in Great Passage Street. The buildings (a perspective and a plan of which were given in last week's issue) are situated in close proximity to the docks in the centre of the city, on a site recently occupied by closely-packed tenements. Provision is made for forty families in self-contained flats of two, three and four rooms each. Mr. T. Goates, whose contract amounts to £9,750, is carrying out the work under the superintendence of the city architect, Mr. Joseph H. Hirst.

MOUNTAIN CHURCH DESIGN.

THE mountain church design shown on this page, and also as a centre plate, was awarded the prize at the recent Welsh National Eisteddfod held in Liverpool. The prize awarded was a gold medal and a sum of £10. The author of the design, Mr. R. Wynn Owen, says: "There is no doubt that, if it were more generally known the Welsh National Eisteddfod offered several prizes of this kind annually, more architectural students would send in designs for the various subjects. By making this fact known in your journal, a number of junior members of the profession may learn of a new field for competition which up to the present has been practically in the hands of a limited number of competitors."

The National Association of Master House-Painters of England and Wales held its seventh annual convention at Blackpool last week. The delegates numbered 506. Sir Matthew White Ridley, in declaring the convention open, said it was quite true that there had been an influence brought to bear upon decorative art in this country, and great improvement had taken place of late years. He could not imagine anything more backward than the decorative art of the earliest period of Victoria. But we had made progress, partly through the efforts of such associations as theirs, and partly perhaps through the technical education which had been carried on of late in the country. Meetings and conventions of this sort, he thought, were a most valuable means of exchanging ideas, and also of carrying on that kind of educational work which could be done much better by united effort than by individual exertion.

FIRST PRIZE DESIGN FOR A MOUNTAIN CHURCH, WELSH NATIONAL EISTEDDFOD, 1900. BY R. WYNN OWEN.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

R.I.B.A. Preliminary Examination.

COVENTRY.—STUDENT writes: "What are the best books for preparing Subject VII., Elementary Mechanics and Physics, of the R.I.B.A. Preliminary Examination?"

Any modern elementary text-books on the subject will be suitable—e.g., Glazebrook's Cambridge Natural Science Manuals—"Statics," 3s.; "Dynamics," 4s.; "Light," 3s.; "Heat," 3s. (Clay and Son, Ave Maria Lane, E.C.); or Besant's "Elementary Hydrostatics" (Bell and Sons, 4s. 6d.). HENRY ADAMS.

Planning of Schools.

LEICESTER.—C. H. F. writes: "Can you recommend a book on the planning of small boarding schools, say for 60 pupils?"

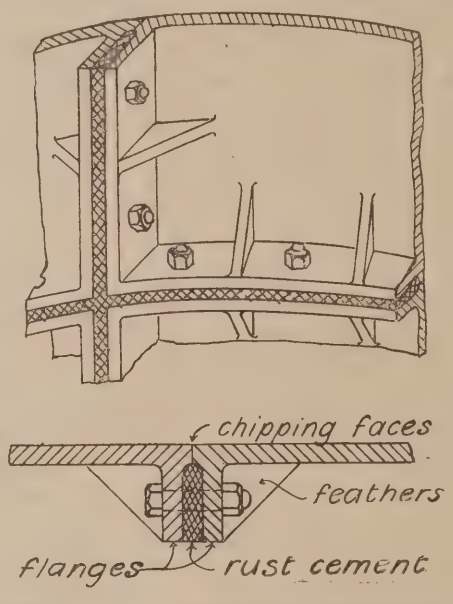
We know of no book dealing especially with boarding schools; we recommend the following books on school planning: "School Architecture," by Palliser, Palliser and Co., 4s. 6d. nett; "Technical School and College Buildings," by E. C. Robins, 18s. nett; and "Modern School Buildings," by W. R. Briggs, 17s. nett. These can be obtained from Mr. B. T. Batsford, of 94 High Holborn, W.C.

The Initials "C.E."

LONDON, S.W.—C. T. writes: "Is there an examination to pass before a person can write 'C.E.' after his name?"

Anyone can use "C.E.," meaning civil engineer, but not M.I.C.E.—Member of the Institution of Civil Engineers. The former is no guarantee of ability, but the latter is.

Scagliola.



GLASGOW.—ANXIOUS writes: "Having some work in connection with scagliola, I am desirous of learning how it is made, and if plaster or cement is used in its manufacture. Can scagliola be used for the imitation of rare marbles?"

Scagliola is composed of superfine plaster which is mixed with various mineral colours, and then gauged with glue water. Keen's superfine cement is used for the manufacture of marezzo, the name given to a more recent plastic imitation of marbles; but with the exception of pressing the coloured cement on plate glass in order to save polishing, the method is similar to that used for scagliola. The colours and quantities used and the methods in the manufacture of scagliola vary for every kind of marble imitated, so that it is impossible to fully describe the numerous processes at command. The principal part in the manufacture of scagliola is the mixing of the various colours in due proportions with the plaster and strong water to suit the marble being imitated. Another important point is the chopping and slicing of the various coloured plastic lumps. The coloured slices and lumps are laid in position—taking care to keep the "figure" and veining similar to the natural marble—and the mass is allowed to set. When thoroughly set and hard it is planed and then stoned with snake stone; the surface is then washed with a sponge, and then any holes or crevices thoroughly stopped. It is then stoned and stopped again until the surface is smooth and solid, after which it is polished with putty powder. This operation is an embodiment of the principle of manufacturing scagliola. It can be made *in situ*, but it is generally made in slabs or blocks, as for columns, pilasters, &c., and then fixed in position. Many of the precious and rare marbles, such as jasper, verd-antique, porphyry, brocatello, giallo-antique, lapis lazuli, &c., have been imitated so minutely, and with such an astonishing degree of perfection, as to defy detection. Scagliola is one of the most beautiful parts of decorative plaster work, and the finest and truest imitation of any natural material used in the building trade. It has the look, colour, taste, touch, and polish of natural marble. Full practical instructions for the manufacture of scagliola are contained in "Plastering: Plain and Decorative," published by B. T. Batsford, 94 High Holborn, W.C.

W. MILLAR.

Foundations.

ILKLEY.—R. F. writes: "(1) Half of a public building, having a total area of 200 sq. ft. and a height of 60ft., is to stand on the site of an old quarry, filled in with rubbish to a depth of 35ft. The rest of the building will be on solid rock 4ft. below the ground level. Half of a tower, 40ft. square and 200ft. high, comes on the rock and half on the filled-in quarry. How would you construct the foundation over the quarry site? (2) What foundation would you adopt for a large church built entirely on sand or loose friable earth (no solid bottom procurable)? Would there be any special treatment for the foundation of the tower? (3) To what depth can wooden piles be driven, and are they always in one piece? (4) To what depth can brick piers be sunk? (5) To what depth can

JOINT OF IRON CYLINDERS FOR FOUNDATIONS.

iron cylinders be sunk, and how are they jointed? (6) Are the foundations shown on the accompanying sketches (not reproduced) ever used by architects; and, if so, on what occasions? (7) Is there any special book on foundations of the above kind?"

(1) The foundations must go down to the solid rock, either by building on brick walls and girders or concrete piers and arches. To build half on solid rock and half on made ground would mean certain failure, however much the footings of the latter were spread. (2) A "raft" of concrete with old rails embedded would give a suitable support if the earth were shut in by sheet piling round the site. (3) Wooden piles can be driven 30ft. to 40ft. in some soils; they are usually in one piece for driving, and frequently scarfed just above the ground or water-level. (4) Brick piers can be sunk to any required depth, but anything over 30ft. would be excessive. (5) Iron cylinders can be sunk to any required depth, but 60ft. below high-water mark is about the limit in practice. They are jointed by inside flanges with rust cement between, as shown on the accompanying sketch. (6) The writer has never seen foundations like those marked A on querist's sketch put in, but, if properly designed, there is no reason why they should not answer. The tie rod would only be required at the end arches. In arrangement B the timbers should be bolted together, and, as a rule, all notching should be avoided. (7) Piled foundations are treated very fully in Adams's "Timber Piling in Foundations and Other Works" (60 Queen Victoria Street, 1s.).

HENRY ADAMS.

Graphic Statics.

REDDITCH.—REX writes: "Is it necessary for me to obtain a book on applied mechanics before studying a book on graphic statics? Also, which is the best book on the latter subject? If I *must* take up applied mechanics, which is the best book?"

Graphic statics, as generally studied, is a subject by itself, and does not need a previous study of applied mechanics. It is one section of the larger subject of mechanics. Such a book as Adams's "Strains in Ironwork" (Spon, 5s.) takes in all that the average student requires to know on the subjects of parallelogram of forces, reciprocal diagrams, stresses and strains, as applied to girders and roof trusses, and is recommended by the R.I.B.A. examiner.

HENRY ADAMS.

Size and Number of Rainwater Pipes.

LEEDS.—J. D. S. writes: "A roof gutter capable of carrying a 6in. depth of water is 1,000ft. long and drains a surface of 30,000 super. ft. horizontal measure. How many outlets of 3in. diameter should there be, assuming a rainfall of 0·0216in. per minute?"

Rainwater gutters and pipes are not usually calculated, but this seems to be a case where some calculation is necessary. Generally 4in. gutters and 3in. down pipes are fixed for private houses, and 4in. to 6in. gutters with 4in. down pipes for public buildings. The down pipes are generally placed in convenient angles or about 20ft. to 40ft. apart, and the gutters laid with a fall towards them of 1in. in 10ft. Under a rainfall of 1in. per hour, 50 times the diameter of pipe in inches squared would give the approximate area of roof in square feet which that pipe would serve—e.g., 4in. pipe, $4^2 \times 50 = 800$ sq. ft.; but in the present case the rainfall would be about $1\frac{3}{10}$in. per hour, so that it would be wise to limit one 4in. pipe to 600 sq. ft. and $\frac{30,000}{600} = 50$ down pipes, $\frac{1\,000}{50}$ = say 20ft. apart. Unless the locality is subject to very concentrated storms of rain 0·0216in. per minute seems rather high.

HENRY ADAMS.

Forming Entry under House.

BIRMINGHAM.—R. L. writes: "It is proposed to provide an entry, 3ft. wide, to go under a house. Kindly say which is best and cheapest method of carrying the party wall, &c.: please also state sizes of girders necessary. The builder who is instructing me proposes to carry the wall on concrete between girders; latter placed at about 2ft. 6in. centres across entry walls. The party wall is about 33ft. from ground-floor level to apex of roof. How can I determine what amount of material is to be calculated as the load coming on certain girders, &c.? Rivington does not show this."

The greatest weight upon any single joist would be brought upon that under one or other of the chimney stacks. Even this, with the construction suggested (which is about the best possible), would be only $6\frac{1}{2}$ tons—assuming a load of brickwork 1ft. 6in. by 2ft. 6in. by 33ft. high at 1cwt. per cubic foot—and this may be taken to be evenly distributed. On consulting Messrs. Dorman, Long & Co.'s table of steel joists, we find that their *light* 4in. by 3in. section will readily take this; and no smaller joists would be structurally sufficient to carry the concrete. In small works which do not involve the use of riveted girders it is generally more satisfactory to consult a manufacturer's handbook of sections and weights than to calculate for oneself. G. A. T. M.

Book on Gothic Architecture.

GLASGOW.—J. W. B. writes: "Can you give me the name of a good book on Gothic—mostly illustrations, with little or no reading matter—the book to give illustrations of all styles, and not be confined to one particular period?"

"Details of Gothic Architecture," measured and drawn by J. K. Colling. This can be obtained from Mr. B. T. Batsford, of 94 High Holborn, W.C., for £2 2s. nett.

Cleaning Pictures and Picture Frames.

GLASGOW.—ARTIST writes: "Please state how to clean and regild picture frames, also how to clean old oil paintings. Would it be advisable to varnish them? If so, kindly state kind of varnish to use."

Cleaning an oil painting is best accomplished by a judicious application of soap and warm water, the picture having been removed from its frame, and care being taken to keep the back of the canvas dry. Most oil paintings are varnished for the sake of protecting the colours; and whilst an extra coat of varnish may do no harm, it may, on the other hand, effect little or no improvement. This matter must be judged by individual circumstances. A painting which has blackened with age, or in which the colours have become dull and indistinct, will stand rather in need of "restoration" as distinct from mere cleaning—the removal of dirt—and this may necessitate the removal of the old varnish and, possibly, several coats of it. If the picture is of any value, it would be advisable to entrust it to an expert in the art. Before the varnish is removed its character must be determined. Mastic is generally used for good pictures, but copal is sometimes employed. The latter can only be removed by an alkali, and extreme care will have to be employed in order that the painting may not also be removed. Further, every trace of the alkali (caustic potash) would have to be got rid of before it would be safe to apply a fresh coat of varnish. Mastic is removed by the aid of rectified spirits of wine, three or four parts of this being reduced by the addition of one part of turpentine, the mixture being thoroughly agitated, and applied by means of small pads of cotton wool. Here, again, great care has to be exercised to prevent damage to the painting after the varnish has been dissolved away; and directly the paint is reached, the spirit should be wiped away with a clean pad of cotton wool moistened with turpentine only. One or more coats of new varnish may be applied—mastic varnish thinned with turps being used—and each coat must be put on as thinly as possible. Hydroxyl is sometimes employed in picture-restoring. This is a compound of hydrogen and oxygen, and it acts upon the blackened picture by converting the lead sulphide into lead sulphate. For cleaning a gilt picture-frame previous to regilding, soap and water applied with a soft brush will be found efficacious. The frame is then to be thinly coated with gold size, evenly applied; and when it is dry, but still tacky, gold leaf can be laid on in the same manner as in ordinary gilding, or the frame may be dusted over with bronze powder. The latter, however, will soon discolour unless protected by a coat of spirit varnish or lacquer.

Air-Pump Ventilators.

TUNSTALL, STAFFS.—TROUBLED writes:—"Great annoyance is caused to a congregation of a chapel owing to the roaring noise of the roof ventilator in times of high wind. Can you suggest a remedy? The ventilator is connected with two ceiling gratings by 12in. metal pipes."

We are of opinion that the noise attributed to the ventilator is the result of the accelerated up-current produced in the shafts leading to the ventilator during high winds. It could be obviated by fixing a regulating valve in the *main* shaft of the ventilator so that the increased velocity of the air-currents produced in the upcast shafts might, under those circumstances, be controlled. The valve would be operated from below by means of pulleys and cords.

ROBERT BOYLE AND SON., LTD.

Price Books.

BOLTON, LANCS.—J. F. C. writes: "Which is the most suitable and reliable builder's price book for this part of the country (London prices are, of course, higher than here)? Also, will you name a good book tabulating the breaking and safe loads of different sizes and strengths of cast-iron and steel columns, stanchions, girders, beams, &c.?"

There is no book giving prices for Lancashire; builders' price books are only approximate, and either "Specification," Lockwood's or Laxton's, will serve equally well as a basis for calculation. Most of the firms supplying structural ironwork publish particulars of the loads their girders will stand. Molesworth's "Pocket Book of Engineering Formulæ," published by E. and F. N. Spon, Limited, 125 Strand, W.C., is a very useful book.

Local Government Plans.

LONDON, W.C.—BUSWING writes: "I should be glad to know if there is any periodical record published giving the plans submitted to local governing bodies in Great Britain for their approval."

We do not know of any such publication: nor do we believe it exists.

Views and Reviews.

Mitchell's Building Construction.

The fifth edition of the elementary course of this well-known text-book has just been published, making its twenty-third thousand. The present edition is almost a new book, fifty pages having been added and the whole completely revised. The illustrations have almost all been re-drawn, and 250 additional ones are included, all of them being now most clear. One of the new features is a useful series of illustrations of the tools used by the excavator, bricklayer, mason, carpenter, joiner, and slater. As an elementary text-book in building construction the book fulfils all requirements, but we would call attention to a few matters which we think might be improved. It would be an improvement if, in the first few opening chapters, almost all the present definite statements were explained slightly, so that students having little or no previous acquaintance with the subject might learn the reason for such and such a procedure. Of course the statements can be explained by consulting other text-books, but we assume that Part I. is intended to be complete in itself. For instance, on page 13 we are told that a wall is protected from damp rising from the ground by a horizontal course of damp-resisting material laid at a distance of 6in., or not more than 1ft. above the ground level. These measurements should be explained; the book is not a specification. The same thing occurs with regard to bonding brickwork on page 18, and with the statement (on page 24) that bricks in footings should be laid as headers as far as possible. Why not state that the reason for using headers is because an offset over a stretcher allows a bearing of only 2¼in. for the top brick? Also, if the reasons were stated why 2¼in. offsets for the bottom course of footings in a two-brick wall are needed to be four bricks wide, and why it is necessary to double the bottom courses of footings, the student would understand these matters better. We are glad to see that only "essential" dimensions are given on the diagrams. A new chapter has been added upon "Building Quantities," with some general memoranda on the various trades. We would point out that on page 5 the lettering in the text is not the same as that on the illustration; also that the first line on page 24 requires the word "or" between "two" and "more"; also that "bye-laws" should be spelled "by-laws." But, after all, these are slight inaccuracies. The book as a whole is very carefully and lucidly written; students could not obtain a better work on elementary building construction.

"Building Construction and Drawing: First Stage or Elementary Course." By Charles F. Mitchell. Fifth Edition. Price 3s. London: B. T. Batsford, 94 High Holborn.

A Dunfermline Competition.—The joint committee in charge of the erection of the new Carnegie Baths and Gymnasium at Dunfermline have invited competitive plans from local architects and from Mr. J. M. Brydon (London), Mr. David Barclay (Glasgow), Messrs. Ross and Macbeth (Inverness), Mr. H. I. Blanc (Edinburgh), and Mr. William Williamson (Kirkcaldy). The total cost is expected to be £17,000.

Builders' Notes.

Building at Blackpool.—There were thirty-two plans, as compared with forty-two for the same period last year, submitted at a meeting of the Building Plans Committee of the Blackpool Town Council. Of this number the following were approved:—Two houses in Banks Street; eleven houses and stables in Whitegate Lane and Palatine Road; two houses and shop, Benson's Lane; six houses, Palatine Road; house and stable, Cow Gap Lane; two houses, Palatine Road; six houses, Manchester Road; new school, Devonshire Road, Blackpool School Board; lock-up shop, Coronation Street.

Breaches of Building By-laws.—Mr. H. Howarth was charged at the Blackpool Police Court recently with three offences against the Borough building by-laws, in respect of premises in Church Street, South Shore. One shop had been converted into two, and the place had been let to a London firm, who had carried out the alterations regardless of expense. Mr. Howarth said he did not know until he heard from the authorities that there had been any infringement. He sent in plans as soon as he knew, but they were disapproved. The Bench decided that defendant had not had sufficient knowledge of the by-laws, and only imposed a penalty of £1 and costs.

A Heswall Builder Fined.—Mr. Emmanuel Ellis, a Heswall builder, was summoned recently for violations of the Wirral District Council's by-laws. It appeared that the defendant had not given notice of his intention to erect a cottage in Liverpool Road, Heswall; the thickness of the external and party walls was but 9 inches instead of 13½ inches; and the air-space at the back, which the by-laws stipulated should extend laterally for 20 feet in the case of a building such as the defendant was erecting, was only 15 feet. The Building Surveyor said the defendant had defied the Council in the matter. Defendant was fined £1 with 8s. 6d. costs in each of the three cases.

Dissolutions of Partnership.—The partnership heretofore subsisting between Messrs. John Mason, of 40 King Street, Egremont, in the county of Chester, and Arthur Mason, of 8 Ferndale Avenue, Liscard, Chester, builders and contractors, carrying on business at 2 Union Street, Egremont, Chester, under the style or firm of J. Mason and Son, was on the first day of September, 1900, dissolved by mutual consent. All debts due to and owing by the late firm will be received and paid by Mr. John Mason.—The partnership heretofore subsisting between Messrs. John Groves and Charles Edward Smith, carrying on business as joiners, builders and contractors, at West Hartlepool, under the style or firm of Groves and Smith, has been dissolved by mutual consent as and from the 19th day of September, 1900. All debts due to and owing by the late firm will be received and paid by Mr. Charles Edward Smith.

The Building Trade of Newquay seems not to be so bad as would appear from the note in our last week's issue. Although things are a little quieter than has been the case for some time (because there are so many "builders" putting up terraces on terraces), there is still a good amount of work going on. The two houses of Mr. Tippetts are nearing completion, as are also a new Claremont Sunday School, a Devon and Cornwall bank, and three houses on the Island Estate. The contract has been let for a large house for Dr. Hardwick on the latter estate, and a new drill hall is to be built for the local volunteers. Mr. John Ennor, jun., has three large houses in hand on the Penhre Estate, is completing a terrace at Springfield, and has also prepared plans for two large shops in Bank Street, the site of which is now being excavated. With the proposed new hotel, for which the licence is granted, and with what we have mentioned above, things in the building line are fairly brisk.

Change of Address.—Mr. Ernest T. Marriott has removed from 3 Clifford's Inn, Temple, E.C., to 10 Great College Street, Westminster.

Keystones.

A New Infirmary at Shifnal is to be erected at a cost of about £2,200.

Two Stained-Glass Windows have been placed in the apse of St. David's Church, Neath.

Plans for a New Theatre at Aston, in the Lozells Road, have been passed by the District Council.

Little Portland Street Chapel has been re-opened, after extensive renovation and improvement.

A New Academy at Linlithgow has been erected on a prominent site adjacent to the Palace Grounds by Messrs. R. and W. Philip, contractors, of Linlithgow.

Anwick Church, near Sleaford, has been re-opened after considerable restoration and improvement. The chancel has been raised to its original height, and the east end considerably altered.

A Screen at St. Thomas's Church, Newcastle, has been erected to commemorate the Novocastrians and Northumbrians who have died in South Africa. A new reredos has also been placed in the church.

The Girls' Recreation Club at Exeter has been extended by the addition of a new wing, which was opened by Lady Audrey Buller on September 29th. The builder was Mr. William Brealy and the architect Mr. Harbottle Reed, both of Exeter.

A new Baptist Church at Newcastle-on-Tyne is being erected by Mr. A. Bruce, builder, of Newcastle, whose tender is £4,383 3s. 6d. The architects are Messrs. George Baines and Reginald Palmer Baines, of 5 Clement's Inn, Strand, London, W.C.

A Joint Isolation Hospital for Nantwich is proposed to be erected by the Rural District and Urban District Councils. The scheme provides for the erection of a hospital and the provision of sixteen beds, twelve for the rural and four for the urban district.

In Memory of Ruskin.—A Society of Arts tablet has been affixed to the front of the house in Hunter Street, Brunswick Square (No. 54), in which John Ruskin was born. The house is three doors from the junction of Great Coram Street with Hunter Street.

The New Workhouse at Grove Park.—Mr. Thomas Rowbotham, of Small Heath, Birmingham, has recently commenced the erection of a new workhouse for the Greenwich Union at Grove Park, Kent, at a contract cost of £175,020. The selected plans of this building were chosen by the Local Government Board for exhibition at the Paris Exposition, as representing one of the most modern institutions of its kind in the United Kingdom.

A New Chapel at Penmaenmawr.—As soon as the plans which have been submitted to the Urban District Council have been passed, the erection of a new Welsh Calvinistic Methodist chapel will be commenced at Penmaenmawr, at a cost of £5,000. The site adjoins that of the English Congregational Church, and the building will accommodate 750 worshippers, and will be fully provided with schoolrooms, vestry-room, library, classroom, cloakroom, &c. Mr. J. S. Coverley, chairman of the Urban Council, is the architect.

The L.C.C. Shoreditch Technical Institute commenced its second annual session last week. During last session 830 students took advantage of the various classes. The evening classes afford instruction for men and boys in brick-cutting, builders' quantities, building construction, carpentry and joinery, drawing and design, electrical wiring and fitting, French polishing, plasterers' work, tailors' cutting, upholstery and woodcarving; also in inorganic chemistry, heat and electricity, practical mechanics, workshop geometry and mensuration. Full particulars may be obtained from the Secretary of the Institute, Pitfield Street, N.; or from the Secretary of the Technical Education Board, 116 St. Martin's Lane, W.C.

St. Andrew's Church, Ham Common, Surrey, is having a chancel added.

A New Church at York is to be erected in the Foundry district at a cost of about £3,500.

All Saints' Church, Eastworth, Chertsey, is being erected in the Gothic style by Messrs. Goddard and Sons, of Farnham, from plans by Mr. J. Henry Christian, and when completed will seat 500 persons. The cost will be about £6,000.

Public Baths for Wandsworth.—The Lord Mayor of London (Sir A. J. Newton) on Saturday laid the foundation-stone of the public baths to be erected by the Vestry. The baths are on a commanding site facing High Street, and very near the Town Hall. The cost of the building and freehold will be £29,291.

A bronze statue to Admiral Blake has been erected on the Cornhill, Bridgwater. The statue has been executed by Mr. F. W. Pomeroy. There are appropriate panels on the pedestal, representing the taking of Santa Cruz and the bringing home of Blake's body to Plymouth Sound. The cost of the statue has been £1,200.

A new London Restaurant.—After some two years have been occupied in the process of construction, the Throgmorton Restaurant of Messrs. J. Lyons and Co. has been completed. An excavation to the depth of 50ft. has enabled the builders to provide a number of spacious saloons on two floors below the street level, while under these again is another floor devoted to cooking, service requirements, and cellarage.

A memorial to John Ruskin at Friars' Crag, Keswick, was unveiled by Mrs. Arthur Severn last Saturday. The monument consists of a simple monolithic block of Borrowdale stone, rough and unhewn as it came from the quarry. It is of the type of the standing stones of Galloway, which are the earliest Christian monuments of the Celtic people now extant. Upon one side is incised a simple Chi-Rho enclosed in a circle after the fashion of these earliest crosses. On the other side of the monolith, facing the lake and the scene which Ruskin once described "as one of three most beautiful scenes in Europe," is a medallion in bronze, the work of Signor Lucchesi, representing Ruskin as he was in his prime, in the early seventies.

The Birkbeck School of Art commenced its new session last week with an exhibition of students' work, under the direction of Mr. Alfred Mason. Mr. W. E. Tanner takes three prizes for drawing and painting from life. A Queen's Prize for design, chiefly for stained glass, went to Mr. W. Sidey; and a South Kensington prize for silver and enamel designs, patterns for book covers, &c., to Miss May W. Ware. Miss Clarice Carter exhibited silversmithery; and a fresco by Miss Dora Matthews, founded on "A Winter's Tale," aims at the adornment of a proscenium. Panel ornamentation for stained wood and gesso was represented by Miss Elsie Knight, and architecture by Mr. F. Schofield. The number of names on the school register for the past year reached nearly three hundred, the majority belonging to the evening classes.

Church Decoration.—Sir W. B. Richmond, R.A., addressing a meeting last week of the parishioners of St. Peter's, Hammersmith, convened to consider the question of the internal decoration of their church, said he would not advise them to cover the whole church with designs. He would suggest that it should be made lively instead of dead, and for a church that was not to be profusely decorated with colour nothing would be more effective than white. His proposal was white and gold for the body of the church, as good a piece of tapestry for the east end as could be got, and a painting by himself at the top. Beauty and religion had always gone hand in hand, but in these days a party was endeavouring to draw back the mind of man from the contemplation of the beautiful. It was the educational progress of the people which made them desire more beauty. But they must have nothing but what was pure and chaste, and avoid mere cheapness. In addition to the proposed decoration, the vestries at the back of the church are to be enlarged and a parish room formed, the cost being estimated at £800.

Correspondence.

House Planned Like the Ace of Clubs.

To the Editor of THE BUILDERS' JOURNAL.

ILKLEY, YORKSHIRE.

SIR,—I notice a question asked in your issue for last week about a house built like the ace of clubs. Midford Castle, near Bath, was built by Roebuck in 1680, with money won by gambling, and is planned like the ace of clubs, the lucky card on that occasion. The castle was lately in the possession of the Marchesa de San Agneta Conoly, who left her estate to the Roman Catholic Church, appointing the Catholic Bishop of Clifton as trustee; but of these arrangements I am by no means certain. Unfortunately I am unacquainted with the earlier history of the Castle. Your correspondent could now, no doubt, make further enquiries himself.—Yours faithfully,

RUPERT FORD.

Engineering Notes.

Additions to the Union Infirmary, Keighley, are being warmed and ventilated by means of Shorland's patent Manchester stoves, supplied by Messrs. E. H. Shorland and Brother, of Manchester.

County Court, Oldham.—Messrs. John King, Ltd., engineers, of Liverpool, have in hand the warming of this building by means of their "small-tube" hot-water heating apparatus, employing their well-known economical coil boilers.

Change of Address.—The Lilleshall Company, Limited, has changed its address from 12 Lime Street, E.C., to 71 Finsbury Pavement (Electric Railway Station Buildings), Moorgate Street, London, E.C. Its new telephone number is 1691 London Wall.

Projected Engineering Works at Seaham Harbour.—It is proposed to form a company for the establishment of new engineering works at Seaham Harbour, and to take over all or part of the plant and the business connection of the Londonderry Works.

Proposed new Electricity Station for Worcester.—The Electricity Committee of the Worcester City Council, having resolved that it is inexpedient to extend the Powick generating station, recommend that the city architect shall be employed to prepare plans for a new station on a site in Hylton Road and Tybridge Street, which site it is proposed to acquire for £3,750.

Electric Trams in Surrey.—The Kingston Corporation have resolved to oppose a Bill proposed to be promoted by the London United Tramway Company for powers to construct and work electric trams in the borough and in other parts of Surrey. By this scheme the London United Tramway Company propose to lay down trams over about sixty miles of roadway, commencing at Hammersmith and going as far as Esher. There are to be six lines: (1) from Hammersmith, through Fulham, Putney, and Kingston, to Hampton Wick; (2) from New Maldon to Kingston; (3) from the Kingston Gate of Richmond Park to Tolworth; (4) from Surbiton to Esher; (5) from Thames Ditton to Hampton Court; and (6) from Surbiton to Hook. Some of these lines pass through Kingston; and as the Kingston Corporation have a scheme of their own, their opposition is to be "determined and unqualified."

British Institute of Certified Carpenters.—At the meeting held in Carpenters' Hall last Saturday, Mr. J. Clark, vice-president, in the chair, the following gentlemen holding the necessary qualifications were elected members: *As Fellows*: J. F. Maskill (Sheffield), J. Sandham (London), E. W. F. Inn Signs by Painters.

In these days of the revival of arts and crafts, of the strenuous revolt against the commonplace, and against the infinite repetition of outworn themes, the cult of the specially-designed inn sign has become greatly honoured. We have recently seen how Mr. Walter Crane has enriched the little Hampshire village of Grayshott with his decorative sign for the "Fox and Pelican" inn, and about two or three years ago the Marchioness of Lorne designed a pictorial sign for the "Ferry" inn at Rosneath. These are only isolated instances, but there are not a few remarkably good signs executed by well-known painters in different parts of the country serving to give an abiding interest to the villages and hamlets where they may be found. Of course, the classical instance is that of the "Royal Oak" sign, painted for the inn of that name at Bettwys-y-Coed by David Cox, and long since removed to a private collection; but there have been many others. J. F. Herring, coachman first and painter afterwards, was the author of many pictorial signs at Doncaster, which have, almost without exception, been purchased and removed by connoisseurs. Millais, too, in his younger days, painted a sign for an inn on Keston Common, which may now be sought in vain. The list of vanished artists' signs might be extended, but more to the purpose is some account of those which still exist to carry on the pleasing custom. Goring-on-Thames rejoices in the pictorial sign of the "Miller of Mansfield," painted by Marcus Stone, R.A.; and Wargrave-on-Thames has an elaborate one by G. D. Leslie, R.A. In a gossippy book of reminiscences Mr. Leslie tells how this sign came to be painted. "It was during our stay at Wargrave," he says, "that my friend Mr. Hodgson and I painted Mrs. Wyatt's signboard for her—the George and Dragon. I painted my side first, a regular orthodox St. George on a white horse, spearing the dragon. Hodgson was so taken with the idea of painting a signboard that he asked me to be allowed to do the other side, to which I of course consented, and, as he could only stop at Wargrave one day, he managed to do it on that day—indeed, it occupied him little more than a couple of hours. The idea of his composition was suggested by Signor Pellegrini, the well-known artist of 'Vanity Fair.' The picture represented St. George, having vanquished the dragon and dismounted from his horse, quenching his thirst in a large beaker of ale. These pictures were duly hung up soon after, and very much admired. They have since had a coat of boat varnish, and look already very Old Masterly. Hodgson's, which gets the sun on it, is a little faded; but mine, which faces the north, towards Henley, still looks pretty fresh."

The Thames-side villages are especially favoured, for the "Row Barge" at Wallingford also has a sign painted by Mr. Leslie. That inn is a very modest and a very ancient house of entertainment. A document is still extant which sets forth how the license was renewed in 1650, when, owing to the puritanical ways of the age, many other houses in the same town had to forfeit theirs and discontinue business. Once the property of the Corporation of Wallingford, it seems to have obtained its unusual name from having been the starting point of the Mayor's State barge. With these facts in mind, the artist painted an imaginary State barge, pulled by six sturdy watermen, and containing the Mayor and Council of Wallingford, accompanied by the mace-bearer, who occupies a prominent position in the prow. This does not quite exhaust the list of riverside places thus distinguished, for "Ye Olde Swan," Preston Crowmarsh, has a sign painted by Mr. Wildridge. It overlooks one of the prettiest ferries on the river.

Two modern artistic signs owe their existence to a lady. These are the elegant devices

LONDON STREET ARCHITECTURE.

of the "Smoker Inn" at Plumbley and the "Windmill" at Tabley, both in Cheshire. They are from the brush of Miss Leighton, a niece of the late Lord de Tabley. The "Smoker" by no means indicates a place devoted with more than usual thoroughness to the use of the fragrant weed, but it is named after a once-famous racehorse belonging to the family over eighty years ago, whose portrait is seen on the sign. The reverse side of the board displays the arms of the De Tableys, supported by two ferocious-looking cockatrices. From every point of view the spread of this fashion is to be encouraged, for it not only creates an interest in the different localities, but serves to perpetuate local history and legend, and affords the decorative artist an opportunity.

C. G. H.

Bohemianism in Architecture.

IF Bohemianism merely suggests lazy carelessness and luxury, we shall find it strikingly indicated in the porticoes and balconies, verandahs and awnings, flat roofs and sun-blinds, of the wealthy Italian nobleman: from the days of ancient Rome and Pompeii to the present day. The delightful plans of the Pompeian houses (in which the interior quadrangle idea is fully developed) suggest the height of Bohemianism in the sense just indicated, and they are probably the most luxurious types of habitation the Roman nobles were accustomed to: types of a house indicating a life of ease and sensuality which the Romans above all took to so readily. But this is all Italy. How voluptuous, how florid! Surely we can step a little higher in the scale and find a truer Bohemianism, developed from that great and glorious "Northern Energy" which has resulted in the Gothic of Northern Europe. A wild disregard of rules, a cunning playfulness, and a rare spirit for the grotesque are what we find in the great works of Mediæval Europe. And all resulting from the essence of Bohemianism—disregard of convention, comfort before beauty and uniformity, and a total absence of hesitation. So the errors that could not help being perpetrated in work done on such a principle as this we forgive with delight. To come down to our own days; Bohemianism is assuming a more artistic and respectable garb—at least what we call Bohemianism, but it is really time that a new definition should be given to the phrase. It is too delightful a word to be given over to the life of the Quartier Latin or the various doubtful phases of literary life: it deserves to be the appellation of those persons who manage to combine work with pleasure, art with comfort, and beauty with simplicity; and in such a way our homes are surely developing and the spirit of Bohemianism being made manifest. How far are we in actual life from Queen Anne, and yet how short in history! We have actually begun to learn that it is useless and barbaric to adorn our exterior walls with a mass of ornament, and slowly but surely our exteriors are beginning to show to the stranger the comfort that he will meet with inside. It is easy, with a plain grey wall, simple cornice, rugged chimney stack and buttress, modest windows and doors, to represent the most delightful of "sanctums" inside, with cosy corners and hospitable quarters. And this is the true Bohemianism we find in evidence in the new homes of a rising artistic civilisation.

M. J.

On Reflection.

The Knowledge of Materials.

To find architects who know surprisingly little about the practical handling of the materials they employ is not difficult nowadays, and the scheme of Mr. Frederick Batchelor, F.R.I.B.A., President of the Architectural Association of Ireland, is therefore most commendable. He intends to organise in Dublin a regular series of technical demonstrations in order that the architectural student may have the chance of acquiring a personal knowledge of the building trades. Occasional visits to yards and workshops have of course been made for years past, but, though even these are capable of effecting much improvement, the fact that they are unsystematical renders them of less value than a course of visits such as that referred to. The method of specifying certain materials for use in a building simply according to precedent is sadly in need of reform: and we therefore welcome all schemes like the one under notice.

After Six Hundred Years.

DESPITE the hue and cry which has been raised during recent years, there are still among us in surprising numbers men who follow in the steps of that Teutonic race by which Rome was pillaged in the fifth century, and many of its literary and artistic treasures destroyed. The mark of the beast is not gone yet, and the vandal—now man of commerce, now corporation, and, alas! now architect—never fails to seize a chance for accomplishing his work, with a total disregard for the value of the past. Sometimes the vandalism is committed under the impression that a material improvement or a work of necessity is being effected, for proof of which one has only to turn to the "Book of Restorations." At another time a body of men, whose duty it may be to govern the affairs of their town or city, carries on the time-honoured neglect of what the past has left us; and then we find, as at Newport in Monmouthshire, a Norman castle used as a brewery, with (though this has now been removed) a huge board stretching across the top of the old tower displaying in 5ft. letters the title of a music-hall. At other times the vandal does his work in ignorance, though he is not the less culpable on this account: again he may be one who actually sees nothing admirable in the old building which puts his new shop premises to shame: but the list is a long one, and there is now no need to extend it further. For the foregoing is written prefatory to some particulars of an act of vandalism to which our attention has been drawn by a correspondent, and by which Warwickshire has lost an object of historical and archæological interest and value. Until recently there stood near the south side of Great Woolford Church an old house, which, so far as the thick covering of ivy would enable one to judge, appeared to be of the thirteenth century. Unfortunately a large part of the exterior was, because of the ivy, hidden from sight, and one gable end was blocked by a cow-house. It had, nevertheless, an unmistakable air of antiquity, even if a window of the thirteenth century had not been conspicuously present to confirm the first impression. Of that house only one gable remains: from within it is seen to contain a remarkably fine Norman window of two lights under an enclosing moulded arch which rests on shafted jambs with carved capitals. But it is obvious that this gable has only so far been spared because it forms the end to the cow-house. It is difficult to believe that anybody could deliberately destroy a house of the thirteenth century which remained in generally substantial condition, but it is too late now to do more than protest against such neglect and vandalism. Warwickshire has lost a rare and most interesting relic of early domestic architecture. "I was told," says our correspondent, "that the thick walls had served usefully as a quarry for some time past, but the site is still strewn with fragments of mullions, transoms, sills, &c., from windows of the fourteenth or fifteenth centuries, and with many other details in freestone." Such facts speak for themselves: nothing else needs to be said, except to express astonishment that someone in the neighbourhood, archæologist or architect—and there is no lack of either in Warwickshire—should not have been able to prevent a fine specimen of a house built six hundred years ago being demolished on account of the claims of a modern cow-house.

The L.C.C.

IT took Mr. Dickinson an hour and a half last week to tell his colleagues on the London County Council what work had been accomplished and what was to be done in the future: the address, which will be found on another page, is an instructive one. The most paramount matter is of course that of housing the working classes, the necessity for which has been urged by every politician during the present election. The members of the respective parties have called one another nasty names, and have thrown a lot of mud; but it is a universal conviction that some really effective and extensive measure must be passed to thoroughly deal with the problem which, as yet, the statutes have only capered with, patching here and mending there and muddling elsewhere; but they have brought things to a climax, and the future offers much hope. Being the governing body of such a city as London, the Council's housing problem has necessarily been the most complex. The difficulties have been stupendous, the expenditure enormous; that, however, all belongs to the past. The Council, by determining on a strong progressive policy, has a new era opened to it—an era of ever-brightening improvement. The amount of money spent on working-class buildings completed within the past twelve months was £370,000 (which is three times as much as that for any previous year); then allow £350,000 for buildings ordered but not yet out on contract, and £1,500,000 for other building schemes not finally approved, but more or less in a forward state; and this gives us a total of nearly two and a quarter millions of money, which is a good start on the new road. To show how decidedly more comprehensive are the schemes completed during the past year, or about to be begun, it may be pointed out that these alone provide for the rehousing of 50,000 persons, whereas all the previous housing schemes since the inception of the Council eleven years ago have only provided for about 10,000 persons. Under the present strong policy, aided by wise legislation, we may expect really great improvements in the housing of the poor. Another matter of importance which came before the Council last week was the scheme for widening Piccadilly to about 170ft. between Hyde Park Corner and Walsingham House. This will be done by taking a strip off the Green Park, land which will cost the Council nothing. A good comparison is offered by the Hôtel Cecil widening of the Strand in 1896; though it only embraced a strip of vacant land 225ft. long, the cost was £30,000, and this was considered cheap. For the same amount Piccadilly can be widened for half a mile. If the widening were effected on the northern side instead of on the southern, it is estimated that the cost would be a million and a half! But, after all (as we pointed out some time ago), the advantage of this widening is more apparent than real, and we doubt very much whether it will prove such a blessing as the Improvements Committee thinks.

A COTTAGE, OMBERSLEY.

SOME OLD WORCESTERSHIRE HOUSES.

THE county of Worcester affords examples of some of the best half-timber work in England. It has quite a character of its own; there is a quiet charm about it which is perhaps more pleasing than the considerably more ornate work to be found in Cheshire, where the contrast between the dead black of the oak and the pure white of the filling is, to say the least, somewhat harsh.

It is, indeed, open to question whether at the time most of the half-timber work was executed it was invariably the custom to distinguish the wood and plaster by this very violent contrast; on the contrary, there is reason to believe that various tints were used, and that the woodwork was not blackened until rendered necessary by the decay which took place in subsequent ages. There is in existence an order by the Common Council of Worcester, on the occasion of one of Queen Elizabeth's public progresses, to the effect "That every inhabitant within the liberties of the citie shall forthwith whitlyme and colour their houses with comely colours. . . . The fower gates shall be sett in some decent colour, namely, in an ashe colour." In humbler buildings it was not unusual to cover the whole of the wall surface, both plaster and timber, with a uniform yellow wash.

Arriving at Tewkesbury, one has not far to search for half-timber houses, which are mostly to be found in the three principal streets. The many examples of domestic work strikingly illustrate the commercial successes of the town in the fifteenth and sixteenth centuries, which only gave way to the supremacy of Bristol in the seventeenth century.

Within a few miles of Tewkesbury there existed until a few years ago one of the most perfect examples of late Elizabethan half-timber work to be met with in England—Severn End, the seat of Sir Edmund Lechmere, Bart. This old house, which consisted of an extensive group of buildings forming roughly three sides of a quadrangle, was burnt down in October, 1896, together with its ancient furniture, pictures, manuscripts, and books.

Another interesting example is Eastington Court, about three miles from Upton-on-Severn, formerly the manor house, but now a farm. The building has unfortunately been allowed to get out of repair. It dates problably from about the time of Henry the Seventh, and is thus one of the oldest examples of a timber-built manor house to be found in the county. With the exception of sundry coats of paint and whitewash, it has undergone little change. The general design of the principal front is particularly pleasing; the assortment of gables—some carved with a vine pattern—together with a huge ivy-covered chimney, forms a charming group. Within the house many changes have taken place, but the hall still remains, with the oak screen in its original position.

We now cross the Malvern Hills to Ledbury, a place of pilgrimage for all readers of the poetry of Elizabeth Barrett Browning, who, at Hope End, not far from here, spent many years of the early part of her life. Ledbury to-day is an old-fashioned agricultural town which has seen few of the changes that have so altered the appearance of some of its neighbours. Its curious half-timbered market hall, restored in 1866 and elevated on sixteen oak pillars, its wonderfully fine old church, which exhibits various stages of architecture, from Romanesque to Perpendicular, and its excellent old houses are not only interesting in themselves, but the general aspect of the whole place is particularly pleasing. A narrow lane, lined with half-timbered houses, leads up to the church, and forms in itself a charming picture of mediæval England. History tells us that Ledbury was the centre of many military engagements during the Civil Wars. Prince Rupert made it his headquarters, and resided in one of the old half-timbered houses belonging to the family of Skynner.

The road from Ledbury to Worcester crosses the Malvern Hills by Herefordshire Beacon, and, skirting the foot of the hills, soon brings us to Madresfield Court, an interesting half-timber house lying about a mile to the right of the high road. The original parts of this Elizabethan house have been restored and additions made to blend as well as possible with the old work, The long gallery has been rebuilt in its original position, and the dining-hall, which is the full height of the house, occupies the place and retains the position of the old hall. The most interesting part of the city lies between the market cross and the cathedral. The Worcester of mediæval days was largely constructed of oak and plaster work, and, judging by the remains still left to us, there were many good buildings to be seen. The business instincts of the people have, however, had much to do with ridding the city of these fine old houses, and even such a delightful old building as the Commandery is partly used now for business purposes. This Commandery is one of the numerous hospitals for the poor of which Worcester has been possessed. It was in 1524 suppressed by Wolsey, its revenues being used to supplement the resources of his colleges at Ipswich and Oxford. The Commander's House and Great Hall, rebuilt in Henry the Eighth's reign, are all that remain to us now, but the fine hammer-beam roof, with its beautiful carving, and the Minstrels' Gallery are sufficiently interesting to warrant a visit.

There are several good examples of half-timber construction to be seen in Friar Street and the Trinity.

A walk of about six miles, through charmingly wooded country, brings us to the quaint little village of Ombersley. The centre of interest is perhaps the old-fashioned inn, where one has an opportunity of discovering what good Worcestershire cider is.

We are now in a district which within a radius of a few miles contains many old examples of domestic work, foremost among which is Westwood House, built by Sir John Packington at the end of the sixteenth century. The mansion was occupied by the descendants of the Packingtons until about eighty years ago, when the male line became extinct. The present owner of the property is Sir A. F. Godson, M.P.

The design of the entrance lodge, of which there is an illustration in "Gotch," is pleasing. It consists of two buildings, between which are a pair of wrought-iron gates, with an Elizabethan timber screen and canopy over. The

OLD TOWN HALL, WORCESTER.

mansion is a large quadrangular red-brick building of four storeys. A curious feature of the design are the four wings, which, projecting diagonally from the corners, are terminated in square towers: they are said to have been added as an afterthought, although if their date (1592) be correct, they must have been built within a few years of the erection of the main fabric. Of the interior one notices the saloon, which occupies the entire width of the first floor towards the south-east. The elaborately-carved oak fireplaces are of the Elizabethan period, but the ceiling, a specimen of florid plaster-work, is of later date. The hall, which is immediately under the saloon, is of the same size, but not so lofty. A fine oak staircase attracts attention, with its massive balusters, supporting at intervals Corinthian columns surmounted by globes.

A little to the south of Westwood lies Salwarpe, on the river Salwarpe, which joins the main stream of the Severn at Hawford Bridge, about 14 miles below the village. An old half-timbered farmhouse here is very well worth a visit. Continuing our way through the ancient town of Droitwich, we arrive at Mere Hall, one of the most important of the Worcestershire half-timber houses. Access is gained to the elaborate wrought-iron entrance gates by a noble avenue of ancient elms. On each side of the gateway is a quaint Queen Anne summer house. The hall possesses quite a peculiar character of its own. The front elevation is, on a whole, symmetrical, though Mr. Niven, in his excellent work on Worcestershire houses, does not think the present house is as originally planned. The long uninterrupted line of windows in the upper storey of the central part, with the fine small gables above and the deep unpierced space below, is good in design, and gives much character to the place. It is to be regretted that Mr. Habershon (who one would suppose, from his knowledge of half-timber work, would have had more regard for so interesting an example) should have added, in 1823, the turret and sash windows, which detract so much from an otherwise charming building.

Elmley Lovet Lodge is another very fine specimen of half-timber construction. It was held in the reign of Henry the Third by Sir Thomas Lovet, and remained in the possession of the same family for several generations. According to Habershon, the present house stands on a site formerly occupied by the park keeper's lodge. The house was built by the Townshends; the date 1635, together with the common seventeenth century "Nisi Dominus" in the centre gable of the principal front, probably indicates about the time when the whole of the structure as we now see it was erected. Nearly all the lower windows have lost their mullions and been fitted with sashes, but with this exception the place has undergone little change since it was built. An avenue leads from the church to the principal front of the house, which consists of three large gables, the centre one having the before-mentioned inscription; the other two, one of which is in a very dilapidated condition, are fitted with trefoil work, making a very effective design. The other side of the house overlooks the gardens and a bowling green. On the first floor the principal room or gallery has a moulded plaster ceiling of good design, but with this exception and some delicately moulded panelling of the usual type, there remain few of the original fittings.

We now wend our way south to Pirton Court, halfway between Worcester and Pershore. In the reign of James the First it belonged to Sir William Corteyn, who is perhaps best known as the founder of the colony of Barbados. Internally, there is not much of the original character of the house retained, except perhaps some of the panelling remaining in the hall. The most distinctive feature of the exterior is a long low building, largely consisting of upright timber work: the back has a long bay window, ending in a gable in the roof, with half-timber quadrants; the panels immediately under the windows are filled in with modelled plaster work, though this may not be contemporaneous with the remainder of the building.

Photograph by *H. E. Hemsworth.*

OLD HOUSE, ST. JOHN'S, WORCESTER, LOCALLY CALLED "THE ABBEY."

Leaving Pirton Court, after a walk of about four miles, one comes within sight of Pershore tower. The abbey, almost as interesting as its larger and better preserved neighbour of Tewkesbury, was formerly built of wood, and both church and convent have been thrice destroyed by fire—first about the year 1000, then in 1223, and again in 1288. The fire consumed not only the abbey church, but the greater part of the town as well. Pershore bears all the marks of a quietly prosperous old market town. Its wide street is lined with respectable red-brick houses faced with stone, many of them having their windows blocked up—relics of the days of the window tax. We quit Pershore, and, calling at Evesham—where are many old houses, especially in Bridge Street—pass on to Rouse Lench Court, and finish our tour by arriving at Broadway, so coming back once more to the land of stone buildings.

A New Board School has been opened in Addison Gardens, Shepherd's Bush, which has accommodation for more than 700 children.

ARCHITECTURAL CONDITIONS IN THE XIXth CENTURY.*

By F. M. SIMPSON, Professor of Architecture, Victoria University, Liverpool.

THERE is no pleasure without alloy; no honour without its drawback. The prologue and epilogue of the session form the drawback to the honour you have done me in electing me as your president, and destroy the pleasure I should otherwise feel at the distinction you have conferred upon me.

For not only is the honour a great one, to be president of the oldest provincial architectural society in the kingdom—a society which is only second in age to the Royal Institute of London—but it is rendered still greater by the eminence of the previous occupants of the Chair. My knowledge of the Society is of recent date, and of presidents prior to the date of my appointment at University College I cannot speak; but I had the good fortune to come to Liverpool when this chair was occupied by one who has worked long and zealously for the welfare of the Society—Mr. Henry Hartley. For the first time for many years his name is not on the list of the council of the Society; a fact we all deplore, and nobody more so than myself. Since then Mr. Bradbury and Mr. Culshaw, and my immediate predecessors, Mr. Willink and Mr. Ould, by their energy and devotion have raised the value of these meetings, and have greatly helped to extend the influence of the Society and make its power felt in all matters affecting our profession and the welfare and beauty of this city.

In occupying this chair, therefore, I am conscious of the difficulties of my position and of the comparisons which may be instituted, to my disadvantage, between my predecessors and myself. I only ask for your kind indulgence in the mistakes which I am certain to make, and for your friendly support in any difficulties which may be encountered during my year of office. Upon this I feel certain I may rely.

Although it is not in your power to help me in some of my difficulties, of which this opening address is not the least, I am glad to be able to say that, as regards this address, I have received assistance elsewhere and from a quarter least to be expected. There has lately come into my possession a lecture delivered by a professor of architecture in the year 2000 A.D., in which he reviews the architectural work of the century previous to his own, or, in other words, the work of the present time. How I obtained this paper would take too long to explain, but I can assure you that it would be an interesting story to tell if only time permitted. As this is not possible, I will only say that you can imagine the relief I experienced at not being called upon to produce anything of my own after the two able addresses of last year which all of us, I feel certain, have recently been reading with so much pleasure.

The address by this unknown author which I have the honour to present to you to-night is entitled "Architectural Conditions in the Nineteenth Century." The paper it is printed on is much like what we use now, and the type is very similar. It would indeed take a clever expert to detect any differences. It is addressed to the students of ——; here, unfortunately, the name has been torn off. I may mention that here and there words are illegible; which is particularly unfortunate, as they are generally the names of architects or of buildings which the author selects for praise or blame. In some cases, therefore, I have been obliged to slightly vary the wording of some of the sentences, for which I ask your forgiveness.

The address commences, "Ladies and Gentlemen," and this is particularly interesting as showing that at that period architects were not exclusively of the male sex. In fact, I gather from fragments of other papers in my possession that in some branches of architectural work, and especially in the decoration of buildings, female practitioners were in a majority. But that is by the way. Here is the paper.

* Presidential Address to the Liverpool Architectural Society delivered on October 8th, 1900.

The state of architecture in the nineteenth century is difficult to define. The revivals at the end of the previous century had destroyed the last vestiges of traditional art remaining in England, and the architectural world for many years afterwards was divided into two camps, one containing the exponents of the Gothic style, the other of the Greek. This latter revival need not occupy our attention. It was merely an interlude, and had no subsequent effect on architecture. But the revival of Gothic had different results. This is not to be wondered at when we remember that Gothic was an indigenous style, and that the influence of the old mediæval traditions of building had lingered in England almost until the commencement of the century. In the early days of the revival the most English of all the phases of Gothic, that which was practised in the fifteenth century, was the one universally followed. Foreign idioms, so to speak, crept in later, and copies of earlier work were not attempted until the century was half over. It is not my intention to give you a history of the revival, or to describe or refer to the many churches and buildings, beautiful though many of them were, erected in that style during the fifty years when it reigned supreme. That would mean a paper in itself. But one result of this revived interest in Gothic art requires special mention. The middle of the century was the great age of "restorations." For five-and-twenty years, that is to say from about 1850 onwards, the restoring architect carried everything before him. It is difficult for us to realise now the intense fervour with which the work proceeded. The ancient cathedrals were scraped, re-chiselled, re-carved, practically rebuilt. A clean sweep was made of everything that was not Gothic. Even Gothic work itself was not sacred. Portions of buildings of later date than the original erections were in many cases destroyed in order to give place to nineteenth-century versions of what might have been. The parish churches were treated in the same way as the cathedrals. For a clergyman to have an unrestored church was considered as great a disgrace as to have a son who was a convicted felon, or a daughter who bicycled in rational costume. By the end of the century no such thing was to be found in the length and breadth of the land. The enthusiasm for restoration which undoubtedly existed, and which seems almost inexplicable to us now, was not due so much to a love for architecture as to a mixed feeling, partly sentimental, partly religious. The cathedrals appeal to us now merely as fine works of architecture; but 150 years ago they possessed an additional interest. They were then not only architectural creations, they were also historical monuments. Injured as many of them were, through various causes, they were still full of memories of the multitudes which had worshipped within their walls, and of the craftsmen who had laboured to add beauty to them.

Every stone could tell a story. In every bit of carving you could still see the marks of the chisel of the original artificer. The carving was mutilated perhaps, but enough of its beauty remained to recall its original splendour, and in spite of, perhaps partly because of, this mutilation it aroused more enthusiasm and admiration than if it had been unbroken. In those days the churches were full of the work of all ages. Windows which had been altered in order to give more light, or else increased in size to frame the splendour of the painted glass, still stood sandwiched between others of earlier date. Oak benches and screens with crude but interesting carvings by Elizabethan or Jacobean men showed that the churches had not been so neglected after the Reformation as the restorers wished people to believe and strove to make apparent. Pews of the time of Queen Anne or the first George still remained where the squire had sat and slept through the sermon, his gouty leg propped on a fat and comfortable hassock. The old "three-decker" pulpit was still to be seen proclaiming the Protestant trinity of rector, curate, and clerk. The history of England was written in and about these old buildings. It was this history which the "restorers" of the nineteenth century ruthlessly destroyed. Not only this; they also destroyed the glamour which hung around them, making it impossible for future generations ever to experience the same sensations. We owe the restorers a debt of gratitude for preserving these *structures* for us as monuments of architecture, but we can never forgive them for destroying what was to a great extent the principal charm of this old work. If the architects of the time had been less skilful or more self-assertive, we should probably have been more thankful to them. But their knowledge of the art they loved was in most cases too great, their self-renunciation too complete. The latter was worthy of the old monks in whose architectural footsteps they strove to follow. But their very correctness was the cause of the decay of interest in Gothic art which set in even before the end of the century. The more correct their work, the more exact their carvings, traceries and mouldings, the surer was the revival doomed. It was a case of killing through kindness. The problem confronting these restorers was no doubt a very difficult one. To have allowed these old buildings to fall would have been an act of vandalism, and the wane of Gothic enthusiasm was too strong for half-measures. In the case of the cathedrals and large churches it is difficult to see how they could have acted otherwise than they did. But some of the parish churches might surely have been left undisturbed to act as sweet resting-places to sit and dream in, away from the rush of the matter-of-fact prosaic age in which we live. This could easily have been done. These buildings could undoubtedly have been preserved without the elaborate scheme of restoration and refitting to which they were subjected. The money which was spent on them, the thousands of pounds, if not millions, would have been better expended in building new churches alongside them, and allowing the old ones to remain as historical monuments, a little judicious attention preventing their further decay. But the clergy and laity alike would have regarded this as an attack on the esta-

OLD HOUSE, ST. JOHN'S, WORCESTER (SOUTH SIDE, FROM ROAD).

blished religion, and subscriptions would not have been forthcoming. One consolation we have, and that is, that certain buildings were already in ruins before the restoration mania set in. Fountains, Tintern, Glastonbury, still remain to us, as perfect and as beautiful as they were then. In those ruins we can picture the abbeys as they were once, and admire such carving and detail as remain without an unpleasant feeling at the back of our minds that we may be gazing at clever copies and not at the originals. Thank God, they did not attempt to restore these.

In one other respect we have cause to be grateful to the restorers. Their love of archæological correctness destroyed archæology. Our delight in those old buildings is now purely an architectural one. Disputes as to the date of the structure, as to whether a bit of carving is thirteenth or fifteenth century, are no longer possible. The nineteenth century is responsible for all. The old test as to the age of any part—the state of the stone—no longer holds good, unless it be urged that the more decayed the stone the more recent the work. The old materials had become seasoned through centuries of more or less pure atmosphere, before coal was worked and when the population was less numerous, and were consequently able to stand the vitiated air of the later periods to which the newly-worked stone soon succumbed. But this test is by no means infallible, and even if it were, few have the curiosity or leisure to investigate the matter.

To the age of revivals and restorations succeeded an era of experiments. The period between 1875 and 1900 was marked by most interesting work, ecclesiastical and domestic, but a recognised architectural style seemed more than ever an impossibility. Not only did different architects work on totally different lines, but individual architects often jumped from one style to another with surprising alacrity. It was no unusual thing to find men designing in Gothic one day, in Classic the next, or indulging in their odd moments in a delectable compound called "Queen Anne." They were like children who, with several sweetmeats before them, nibble a bit first from one and then from the other. This architectural jumble was due as much as anything to the changed conditions of the times. The introduction of steam had revolutionised all things—amongst others the methods of architectural study. The old days of the "grand tour" and severe examination of ancient buildings were things of the past. With quickened means of transit came feverish haste in study. Men discovered that they could go to Paris from Saturday to Monday, and to Rome and back in a week. They no longer sat down before a building and laid siege to it with callipers, measuring rod, and tape, mastering every detail and studying every stone, but, sketch-book in hand, were content to jot down "bits" as they hurried along, which might be useful to them afterwards. Sketch-book architecture became for a short time the rage. Flemish gables, German doorways, French windows, and Spanish ironwork crossed the Channel and united to form original architectural designs. It was resurrection pie "à la Continental." It tickled the palate but did not fill the stomach. The phase was shortlived; like all fashions it ran its course, met with its meed of approbation, and then died out. Men, sated with Continental fragments, like truants returned home. Some to their credit had remained staunch to their own country. The Queen Anne movement, which had effected so vast a change in domestic work, reasserted itself, but in a more subdued and chastened spirit. The high priest of the movement, Mr. Norman Shaw, had at the end of the century retired from active practice, crowned with well-earned laurels. But there were many others to carry on the work who, with one accord, united to try and revive the old traditions of English building which had been so completely destroyed by the revivals of one hundred years before. This was the most important movement of the century, and the one that had the most lasting results. It was not universal. There were still those who clung to archæological Gothic and picturesque Elizabethan, and there were others who went to the other extreme and said, "We will have nothing to do with traditional work; we will absolutely ignore precedent; we will return to materials and materials alone, and create our designs out of these and nothing else"—all of which sounded very pretty in a paper, and was received with much applause when enunciated at meetings, but which landed the authors in serious difficulties as soon as they attempted architectural design. The successful architects were those who neither ignored old work nor slavishly copied it; who understood and respected their materials, but who were not above learning from the masterpieces of bygone times.

The many new and different problems the architects had to solve formed one of the great difficulties of the age. In the first half of the century only churches and public buildings were considered worthy of architectural effort. Utilitarian buildings were left to the builder. But with the growth of the æsthetic movement in other branches of art grew the desire for architectural expression in all buildings, irrespective of the uses to which they were to be put. This meant a severe tax on the architects' powers of designing. Without a recognised style, with no tradition to assist them, with an absolutely uneducated set of workmen to carry out their ideas, hampered by work foreign to architecture (such as surveying, valuing, questions of dilapidations, ancient lights, and other semi-legal business, which has long since passed into the hands of a separate class) it is no wonder that they did not always succeed. We flatter ourselves that we can do better now; but then we have their successes and failures to guide us. What the old Gothic and the Renaissance of the "teens" was to them, their work is to us; and in one respect we have the advantage, as the problems we have to solve are not very different from those which exercised them. Some things they did are difficult to understand. To give one single instance only. In the International Exhibition held at Paris in the year 1900 a large building

PARISH CHURCH OF ST. NICHOLAS, DORMSTON.

represented England officially. When one considers that science was represented by its latest inventions, and that the workers in all other branches of art contributed their best and most original work, one would have thought that this building would have been a typical example of English architecture of the end of the century. One would have expected an original design to show what English architects could do. Nothing of the sort was attempted. An old house erected about 300 years previously was carefully copied detail for detail, an exact replica as far as the outside was concerned, and this was the English official architectural contribution. No doubt it was well done; it was the kind of thing they could do then uncommonly well; but I wonder what would be said now if it were proposed to reproduce a building of the nineteenth century as our representative contribution to an exhibition whose object was to advance the arts, sciences, and industries. I do not envy the man bold enough to make such a suggestion. We might not be able to produce anything better, but at all events we could present something of greater interest because it would be an example of the art movement of the day.

The greatest crime of the nineteenth century—but for this the architects were hardly responsible—was the erection of acres of small houses which surrounded all the great cities. Crime is perhaps too strong a word to use when one considers the difficulties which existed. The working man and the city clerk had to be housed, and tenement blocks were few and far between. The English artisan still insisted on regarding his house as his castle, even though the walls would hardly stand an assault from a pop-gun. Two storeys high, and the rooms so low that a popular writer of the day said that the people looking out of the first-floor windows appeared to have their feet on the ground floor, these cottages sprawled over the immediate outskirts of a town, house after house, street after street, a dead level of degrading ugliness. There were thousands of front doors all alike and all equally atrocious, and millions of chimney pots, vents for the polluting smoke from the coal fires then in general use for both cooking and warming purposes. London was entirely spoilt before the century was half over, and the once pleasant old villages which had stood sentinel round it for ages were reached and then engulfed by the stream of "homes for human beings." Other big towns fared no better. Aigburn and Wavertree, round Liverpool, fell into the clutches of the speculative builder. It is sometimes asked why the people were so mad as to allow such things. Why did not the municipalities step in and, by buying up the land round the city, prevent this spreading of their boundaries? If they had done so, our difficulties would not have been so great. The task of forming a zone a quarter of a mile broad round each city, according to its size, such as is now universal—a zone laid out as a park for the recreation of the people—could have been done at a tithe of the present expense if it had been undertaken when the land was still country, or but sparsely built over. But there were difficulties in the way. The money of the corporations was needed for other things. The sanitary conditions of houses in the towns, and of the towns themselves, were in some cases disgraceful. The absence of adequate laws in former years had allowed over-building and overcrowding to a degree hardly credible. To clear out the rookeries was the first object of every corporation, and that engaged much of its attention and most of its money. Another reason was the dislike of the people for tenement houses. Until this was overcome—and it took some time to do it—the law which prohibited buildings being erected within the town itself, and for a certain distance beyond the zone, less than four storeys high, or covering less than a certain superficial area, could never have been passed. A third and most important reason which rendered the "zone" impracticable was the difficulty of communication between town and suburb. In those days there was only the crawling omnibus drawn by horses and the cumbersome train, with its heavy steam-engine and tender for coals, guard's van, and other accessories. Electricity was in its infancy. But as soon as the application of that power became understood and in general use this objection to the zone disappeared. One minute or two minutes longer in a car night and morning was a small price to pay for fresh air and sunlight for a healthy city and a healthy people. This they might have realised sooner than they did.

The extent of a city now is once again defined within lines as clear as those which surrounded the towns of the Middle Ages, but instead of a wall and fortifications there is a park; and beyond the park the suburbs, where in some parts the houses are all detached, the private residences of the merchants and well-to-do middle classes, and in others the tenement buildings of the poorer classes lining wide avenues, housing double the number on half the space possible in the nineteenth century.

With greater height of buildings came of course wider streets. Many more buildings would have come down to us if it had not been for this. It is amusing to read the instructions of 100 years ago: streets had to be at least 40ft. wide, important streets 60ft. wide; and everybody thought that a great triumph had been effected when a new thoroughfare in London from Holborn to the Strand was, after many years' discussion, projected with a total width of actually 100ft. It makes a good street even now, I admit, but we should no longer regard it as an "important thoroughfare."

The difficulties of architects have been already mentioned; but the difficulties of the workmen were still greater. The complaint of the day that the average artisan took no interest in his work, and that it was quite impossible to leave any little detail to him to carry out without a full-size drawing, was a very true one, but it was not the fault of the workman. An architect had opportunities for study denied to him. In the eighteenth century his path had been an easy one. All men designed then much on the same lines—the lines on

THE MOAT, DORMSTON.

which their fathers and forefathers had worked—and it was easy for the workman to keep in touch with the minor modifications which were introduced from time to time. Even for the first half of the century confusion was not so rampant. It is true the styles favoured then were not traditional, but in the Gothic movement at least architects were only too anxious to train workmen in what they believed to be the only possible style. That they succeeded in many cases is proved by the excellence of much of the carving and mouldings still to be seen on such buildings as the Houses of Parliament and the Law Courts, London. But as soon as a number of workmen were beginning to understand and appreciate the feeling of this work, round went the architectural weathercock, and from due Gothic veered to due Classic. Then came the mixture at the end of the century, and it is no wonder that the workman, finding it impossible to understand all the styles, lost touch with his work and ceased to take interest in any. The intelligent foreman who thought for himself, and who would sit, note-book in hand, after working hours puzzling out the solution of a difficulty—the class of man so admirably portrayed by George Eliot in the charming story of "Adam Bede"—gradually became a thing of the past. The old traditions which had been passed on from father to son had disappeared. The apprenticeship system was dead, and nothing existed which could take its place. The technical schools were in their infancy, and although increasing daily and beginning to make their influence felt, had to struggle against difficulties which no longer exist. Fathers had not learnt the value of a preliminary training for their boys. Employers had not realised how much more valuable to them were boys who had received such a training. The trades unions which might have been a good influence were in some cases apathetic, in others unfriendly. Many of the boys, it is true, attended classes; but these were only in the evenings, when the boys were tired after a day's work. Besides, the time spent in these classes was so small that it gave neither teachers nor students a chance.

The situation was well summed up by a leading architect of the day, who, in describing some work carried out in France from his design, said, "The interest displayed by the local workmen in the decorative details was such as may be looked for in vain from the British workmen." It was not that the French workman was more intelligent than the English. It was because the vernacular traditions had not been destroyed there so much as here, and because their technical education was far in advance of that existing in England.

The education of the architects was as defective as that of the workmen. A few years before the end of the century it was publicly stated that there was no architectural education in England, and that in order to meet this deficiency the Institute had started a scheme of examinations. This is probably the most glaring instance on record of putting the cart before the horse. It could only be equalled by a nation declaring war in order to teach its generals tactics and its soldiers how to shoot. There were architectural classes, it is true, sometimes attached to universities, sometimes to art schools, and sometimes under the control of architectural societies. But a preliminary systematic training for students was by no means universal. Schools in which all art students, students of architecture, students in the arts of painting and sculpture and design, and in the crafts allied to architecture, and students whose future would lie in the more humble paths of building, could work side by side and get into touch with one another were few and far between. The pupilage system was still the most common means of entering the architectural profession, although its drawbacks were almost universally recognised. Advertisements were still common in the building papers: "An Architect in practice has a vacancy for a pupil; must be fond of drawing and willing. Premium required." Heaven help the boy who stumbled into such an office. He probably learnt nothing, and his duties were those of an office boy and tracing clerk without the salary of either. Such advertisements ought only to have been printed with the warning signal "Danger" before them.

Many other points might be referred to if only time permitted. We are better off than our forefathers in some respects, worse, perhaps, in others. A good deal of work was done then with which we are now out of sympathy; but on the other hand we must admit that, whether we consider the enthusiasm of the Gothic revival, or follow the history of the Queen Anne movement, or take the last phase of all, the return to purer English Classic, much work was accomplished that commands our respect and admiration. There was plenty of enthusiasm, plenty of originality, and the two combined to make the work of the century, especially towards its close, an extremely interesting link, although rather a twisted one, in the history of architectural progression.

Here endeth the lecture, and I can only add my thanks to its unknown author for the trouble he has saved me, and express the satisfaction I feel that I have been able to place his views before you to-night instead of my own. It is a paper which I hope will lead to a good discussion, although I believe it has not been customary to discuss presidential addresses; still, none of you need hesitate about saying what you think, because your remarks, I am afraid, are never likely to reach the author; and even if they did, you need have no fear of retaliation, as by the time he is able to reply few, if any of you, will be in existence.

A.A. SCHOOL OF DESIGN.

PRELIMINARY MEETING.

ADDRESSES were delivered by Mr. Beresford Pite and Mr. Aston Webb, A.R.A., at the preliminary meeting of the Architectural Association School of Design on Tuesday, the 9th inst., at 56 Great Marlborough Street, W. Mr. W. H. Seth-Smith, President of the Association, was in the chair. Mr. Beresford Pite chose as his subject the study of materials. An acquaintance, he said, with the nature and use of materials for which the architect had to prepare designs—or, more properly, in which he had to design—was of fundamental importance. This acquaintance should extend to a certain knowledge of all those conditions and qualities which appertained to each material that was useful in building work. Such definite comprehension would ally itself to the intention and purpose of the designer, and would procure that harmony between the means used and the end to be obtained which was a proper element of beauty in man's work. A satisfactory architecture could not be produced with unsatisfactory materials, and ignorance of them could not be compensated by any study of the æsthetic forms or details of past architecture. Sound and ingenious construction was an element in beautiful building as important as the right use of material. There should be no confusion of thought as to that art which selected and placed material usefully and beautifully in a building, and the science which attained a constructive end regardless of the means employed. Without constructive science building was impossible, and, unless exercised in suitable materials and with a knowledge of them, good architecture was equally unattainable. As æsthetic design could not exist by itself in architecture apart from building, both of these qualities must be in harmony. Materials, construction, use, æsthetics were progressive in order of study, but each in relation to the other, and beauty in architecture consisted in the harmonious relation of these elements. The effect on the mind in the achieved building was realised in the reverse order. First, the pleasure of the æsthetic quality of form; then satisfaction with its usefulness and dignity; thirdly, its security, fitness and economy of construction; and, lastly, material substance to the whole. Material was constructive unless it was purely decorative, but it was also æsthetic; the quality of texture was little understood in England, though French architects were often capable of giving texture to architecture. This æsthetic element in the workmanship of each building material was of great value to fine architecture, and the neglect of it would be fatal to real beauty. The excellence of material did not enter into this consideration at all. Until the combined expression of form, plan, construction and texture was mastered by the student the decorative use of materials should be dismissed. Closely allied with the utilisation of any material was the workmanship of it, for a design must not only be capable of being expressed fitly in the intended material, but it should be such that the kind of workmanship employed with it should be emphasised and used so as to exhibit its own type of craftsmanship to the best advantage. The workmanship of material should most fitly express the quality of the material, and *vice versâ*. Architecture had for a century been under the spell of an archæological pedantry as unnatural as onerous. Architectural forms had been used because they had been used in the past, not because they were specially applicable to the material. Cleverness in design was the common ideal; it was superficial cleverness, and dangerous to the student and inimical to the progress of national art. The student should begin with a new tradition, and devote practical investigation to the qualities of the materials of buildings and to the craftsmanship of their application to the whole and the parts; and the whole world of constructed buildings lay before him for consideration and study. He would then discern that ancient buildings might contain examples of beautiful treatment of material and of delightful craftsmanship. All the materials in use would yield their different and distinct characteristics to the thoughtful designer. To the student who would sympathetically study and employ them, suggestions for design would be offered which might issue in living character and vitally national buildings.

Mr. Aston Webb said his remarks were only intended for young students. Alertness of mind and preoccupation of subject were qualities which architects had to encourage, and they should carry their powers of observation wherever they went, and not keep them merely for office hours. There was a well-known axiom, that the first thing was to draw, the second to draw, and also the third to draw. That idea had been rather exploded of late; and if the word "design" were substituted for "drawing" it would probably be better. Sketching, beyond a certain point, was almost a dangerous art. Sketching was apt to deceive. The President of the Royal Academy, when addressing the students last Gold Medal day, pointed out that a man's reputation depended finally on his completed work, not upon his sketches. If this was true of painters, to whom the President chiefly referred, how much more true was it of architects! He knew buildings which had been studied too much from the point of view of elevations, and the returns and the general effect suffered. The would find it a great help if from the very beginning they thought in three dimensions. Many persons troubled themselves a great deal as to whether the plan should precede the elevation. He ventured to think that was all twaddle; plan, elevation and sections should be thought of together. Each part of a design should be worked together gradually up towards completion. In addition to that, to make a satisfactory building, that much-abused and much-neglected specification must of course be brought in, as in that were the materials. More than that, such a matter-of-fact thing as the foundation had to be considered; for with a bad foundation the architect would not introduce tall towers but keep his building flat and low, and so his whole design was affected. Mr. F. T. Baggallay had pointed out in a paper read before the Association how often all the features of a building were on the same plane in front. The features of a building when placed on different planes moved differently as one went towards them, and in that way different effects were got. One could not think too much about, or visit too often, a site when making a design for a building. A sketch was too frequently made from a particular point of view, and it was forgotten that the building would be seen from all sides. With regard to simplicity in design, the word as sometimes understood was apt to lead one

astray, and he knew men who prided themselves on the baldness of their designs. He thought what was meant by simplicity was restfulness and repose, for that was the quality wanted in buildings; and that was obtained by a quiet outline, more than by the omission of detail. As to the rectification of optical defects, these were often exaggerated; the entasis of a column was generally too much emphasised, and the stilting of a dome overdone.

Correspondence.

Low Side Windows.

To the Editor of THE BUILDERS' JOURNAL.

LONDON, S.E.

SIR,—I do not often see your admirable paper, but a friend handed to me a copy of your issue for October 3rd, containing an illustrated article, by Mr. J. Russell Larkby, on Warlingham Church, in which that gentleman discusses my much-controverted views upon "low side windows" in churches.

To go at any length into this vexed question would be to tax your space unduly, but some reply to Mr. Larkby's remarks seems necessary.

When I restored Warlingham Church a few years ago I discovered the peculiar cill-niche on the inside of the tiny low side window shown in one of Mr. Larkby's illustrations, and this very unusual adjunct induced me to devote a good deal of time to investigating the unsolved problem of the origin and use of these peculiar openings in churches.

Of ancient documentary evidence as to these, strange to say—although they seem to have been the rule rather than the exception in the churches of most of our English counties—there is little of a direct character. But what there is favours the confessional theory. For instance, there is the well-known letter of Bedyll, one of Henry the Eighth's Commissioners for the Suppression of Religious Houses, who, writing to Cromwell of the twin foundation of monks and nuns at Zion, Middlesex, takes occasion to advise that "the place wher thes frires have been wont to hire [hear] uttward confessions of al commers at certen tymes of the yere *be walled up*, and that use to be fordoen for ever," &c. These outward confessionals were something quite distinct from the grate or grille in an internal parclose screen, whereat the Sisters made their confessions to some of the monks appointed for that purpose; and the obvious construction to be placed upon this passage is that in parochial churches, and probably in some of the monastic and friars' churches, an opening or openings existed in the external wall to which "all comers" might resort "at certain times of the year" to be shriven. This would be from the nature of it an *irregular use*, and as such, specially consistent with the "free lance" character of the friars' missionary methods. They—the Franciscans or Grey Friars especially—received large general powers for the hearing of confessions from the popes and archbishops on their coming to this country in 1224, and as their mission was essentially an itinerant one, they would wander up and down, generally *in couples* (in imitation of our Lord's sending forth of the "Seventy"), resorting to the parish churches and wheresoever else they might meet with the common people. They thus became their confessors *par excellence*, and often, no doubt, came into collision with the jurisdiction of the parish priest, although in some districts, as in Lincolnshire, through Bishop Grosseteste's influence (himself a friar), the two seem to have worked together in harmony.

The real precedent, as I maintain, for these low side windows in churches is to be found in the yet older (in origin) barred and shattered openings in the *external* wall of an anchorite's cell, often built on, like our modern vestries, as a lean-to erection against the north or other wall of a village church. There is irrefutable documentary evidence of such openings having been used by kings and lesser fry who resorted to the recluse, immured for life in his narrow cell, for ghostly counsel, and to make confession and receive absolution. King Stephen, Richard the Second, and Henry the Fifth *we know* (on the authority of Roger de Wendover, Richard of Elmham, and Stow respectively) thus resorted to the anchorite's only medium of communication with the outside world—*a low side window* in all but this its modern name.

And with this earlier irregular use before them, I venture to assert that the friars' powerful influence was sufficiently strong to enable them, "with or without the consent of the parochial clergy" (as the Papal Bull empowering them to hear confessions phrases it), to cause similar confessional windows to be made in the south-west corner of the chancel or other wall of the church. The fact that two low side windows, often of the same date and character, exist in opposite walls of the chancel, or sometimes in the wall of an aisle, seems to me to agree very well with *the fact* that two friars would go about together.

These openings, once made, would naturally come to be used for, and even in process of time specially *made* to serve, other purposes, *e.g.*, communicating lepers, displaying relics to pilgrimages (when the pilgrims were too numerous to come into the church), and *possibly* in some cases to receive a light, or for ringing the sanctus-bell. But their typical narrowness, coupled with the network of iron bars and the wooden shutter with which they were commonly closed, does not favour the two latter explanations; while such features are entirely consistent with the secrecy of the confessional.

The irregularity of the use is quite sufficient reason for our not finding this mode of making confessions represented in ancient drawings and illuminations, whereas illustrations of the normal practice of the parish priest shriving members of his flock while seated in a chair or stall in the chancel are commonly to be met with. A difference of method would naturally distinguish the regular from the irregular usuage.

Confession *at a narrow grated window* is laid down in so many words as the particular mode in the Rule of the Nuns of St. Saviour. And if for them, why not for lay folk in parish churches under certain peculiar conditions? The burden of disproof rests with my opponents, rather than the burden of proof with me.

The sanctus-bell theory (which, by the way, Mr. Ponting did *not* originate; it is a far older heresy) as the normal or originating use of low side windows is absurd, if only from the fact that coeval sanctus-bell cots and low side windows exist together in the same church in many instances.

Doubtless confession would be made kneeling, and for this a bench or stool, placed beneath the low opening, would in some cases be used.

Allow me, in conclusion, to thank Mr. Larkby for the appreciative character of his remarks on the restoration of Warlingham Church, and to invite his consideration of another explanation of the quoins in the north and south walls of the chancel. These slope from top to bottom in a *westerly* direction, proving conclusively that the chancel was built first (by the prior and monks of Bermondsey), and the nave, without any break in its walls, added at a slightly later date. The interesting fact that, besides the usual piscina and sedile in the chancel, there are in the south wall of the nave a plain piscina and sedile, and a similar piscina in the north wall, opposite—all of thirteenth-century date—only proves that when the nave was added to the chancel two chantries were endowed in the nave; or else that the chancel was separated by the screen (of which I found the beam-holes) from the nave and used by a cell of monks, while the piscina and sedile in the nave mark the place of the parochial altar.

Yours truly,
PHILIP M. JOHNSTON.

Manufacture of Portland Cement.

To the Editor of THE BUILDERS' JOURNAL.

MANSFIELD.

SIR,—The answer given on page 159 of your issue for September 26th last to a query in respect of the manufacture of Portland cement is insufficient. It is a well-known fact among cement experts that there are several American patents for the manufacture of Portland cement. Roman cement is used by many plasterers to hasten the setting of Portland cement, especially for running moulding and cast work for ornamental purposes.

Yours truly,
ANGLICE.

Two Specification Clauses.

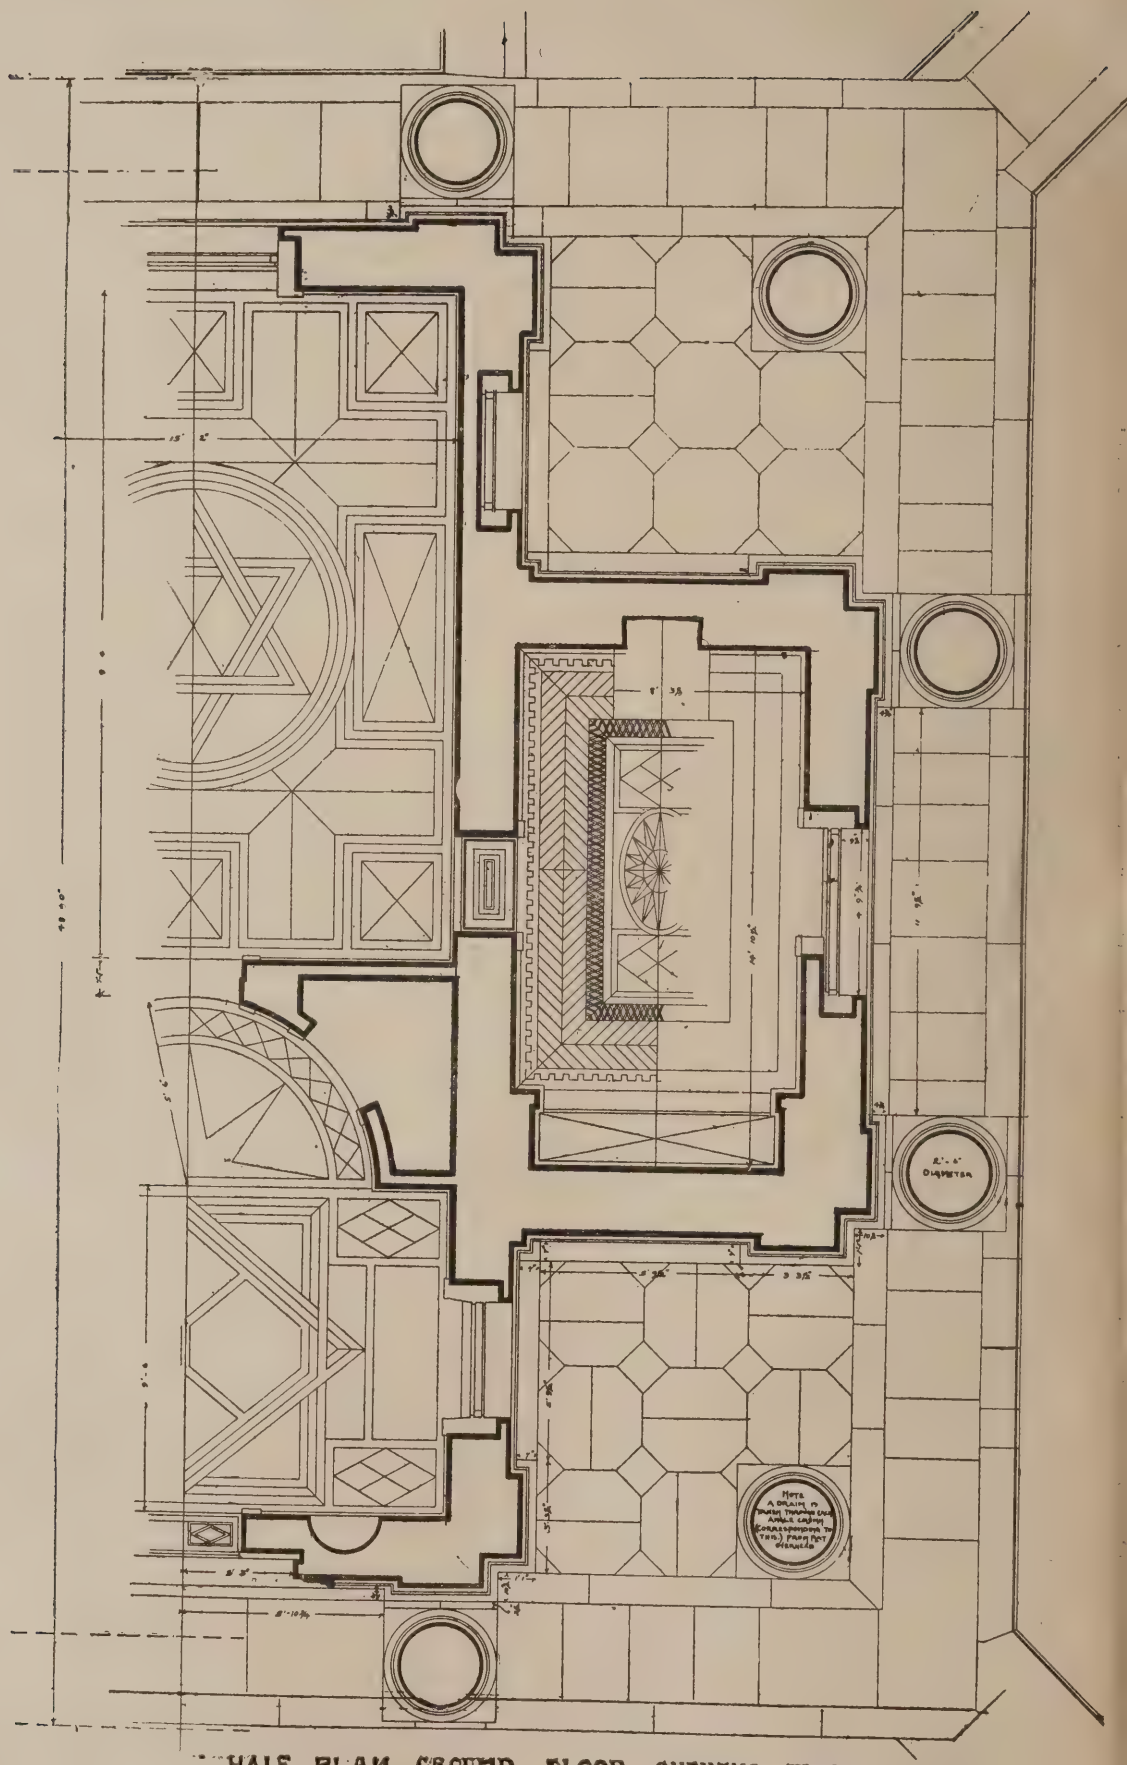
To the Editor of THE BUILDERS' JOURNAL.

ST. ALBANS.

SIR,—The two following specification clauses may be of use to your readers:—*Slate Cisterns.*—Note: Thoroughly wet the slates before finally fixing together, to prevent the cistern bursting through "too tight" bolting. *Fireclay Sinks.*—Note: Care should be taken in fixing plug-waste connections to prevent the sinks cracking through the union nut being screwed up too tight.

I have found, from personal experience, that a fracture has nearly always occurred through the inexperience or thoughtlessness of the workman, and I think this might often have been obviated had a note been made in the specification, calling the foreman's attention to the matter.

Yours truly,
T. W. FISHER.



Builders' Notes.

Scarborough's New Building By-laws have been adopted by the Town Council.

The late Mr. Richard Davie, of Codrington Street, Exeter, who last Monday week attained the age of 100 years and was said to be the oldest voter who had been to poll in the present election, died last week. Mr. Davie was born at Crediton, and at first worked as a mason's labourer. After some years he started business as a builder.

An Apprentice and His Indentures.—On October 3rd, before the Stipendiary at Dale Street, Liverpool, a summons was heard which was taken out by William Gerard against Messrs. J. B. Johnson and Co., of 85 and 87 Crown Street, Liverpool, for non-performance by the defendants of the covenants contained in indentures of apprenticeship by which the defendants agreed to teach the plaintiff the business of a slater and plasterer. It appeared that, having been three years an apprentice, Gerard was dismissed in consequence of continued idleness, disobedience and wilful damage done by him to his employers' property. The plaintiff sought to be reinstated, and asked for a declaration that the indentures were to be carried out. The Stipendiary held that, the plaintiff having by his misconduct rendered it impossible for the defendants to teach him his business, the defendants were entitled to dismiss him, and he thereupon cancelled the indentures.

Dissolutions of Partnerships.—The partnership subsisting between Messrs. Joseph Henry Cashmore and Thomas Cashmore, carrying on business as brickmakers, builders, and contractors, under the style or firm of "J. H. and T. Cashmore," was dissolved by mutual consent as from September 29th, 1900. Mr. Joseph Henry Cashmore will carry on business at the above premises on his own account. All persons owing any moneys to the late firm are required to pay the same to Messrs. Handley, Brown, and Ledbrook, solicitors, 1 Church Street, Warwick, on behalf of the late firm, and all persons to whom any moneys are owing by the late firm are hereby required to send particulars in writing to Messrs. Handley, Brown, and Ledbrook.—The partnership subsisting between Messrs. Frederick Gostelow Lockhart and William Lockhart, carrying on business as coal and builders' merchants under the style or firm of F. G. Lockhart and Co., has been dissolved by mutual consent as and from October 4th, 1900. All debts due to and owing by the late firm will be received and paid by Mr. Frederick Gostelow Lockhart.—The partnership subsisting between Messrs. George Alfred Lewcock and Henry Leonard Clark, carrying on business under the style or firm of H. L. Clark & Co., was dissolved as and from October 1st, 1900, by mutual consent.

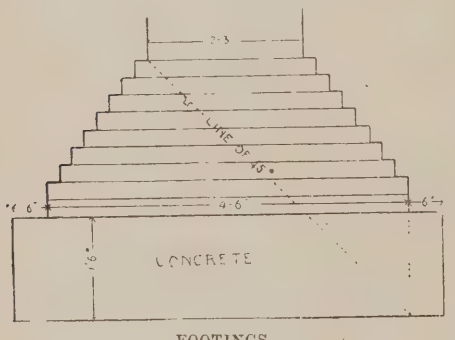
Enquiries Answered.



The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

R.I.B.A. Intermediate Examination.

NEWCASTLE-ON-TYNE. — B. P. writes: "I should be much obliged if you could give me answers to the following questions, set in the last R.I.B.A. Intermediate Examination:—

(1) 'Describe the proper foundation for the walls of a warehouse 40ft. wide, 70ft. long, and five storeys of 10ft. high each, on four different soils—viz., chalk, gravel, sand, and clay.' Are there any easy and quickly applied rules for determining the width and depth of footings to walls?

(2) 'The formula for calculating the weight which a timber beam will carry is $w = \frac{c\,b\,d^2}{l}$. What do you understand by this? And why does the strength of a beam vary as the breadth while it varies as the square of the depth?"

FOOTINGS.

(1) *Proper* foundations would in any case consist of brickwork in footings upon a concrete base, the bottom of the trench being rammed and consolidated. For chalk the site should, if possible, be kept dry, so that the chalk remains solid, in which case the footings may be laid direct upon the levelled chalk; but concrete would be better, especially as the building is a large one. For gravel and clay, as above. For sand—if kept dry and not a "running" sand, in which case sheet piling would be required—the same conditions apply. The easily applied rule for footings is as follows:—Bottom course of footings to be double the width of the thickness of the wall, and each course of footings to project 2½in. beyond the course above. Concrete to project 6in. on each side of bottom course, and to be of such a depth that lines at 45deg. from the junction of base of wall with top course of footings will meet outside line of footings projected vertically downwards in the base line of concrete. (See accompanying sketch.) The bottom course of footings has been doubled, but if this had not been done the concrete would have been 3in. thicker.

(2) It is understood that w = breaking weight; c = constant, the breaking weight of beams $12'' \times 1'' \times 1''$; b = breadth of beam in inches; d = depth of beam in inches; l = length of beam in feet. To show that strength varies as breadth,

Bending moment $= T\frac{bd^2}{6}$, where T = modulus of rupture per sq. in.

Compare four beams, respectively $8'' \times 2''$, $8'' \times 3''$, $8'' \times 4''$ and $8'' \times 6''$, and let T = 3 tons.

Then, from formula $T\frac{bd^2}{6}$

$$(a)\ \text{Beam } 8'' \times 2'' = 3 \times \frac{2 \times 8 \times 8}{6} = 64$$

$$(b)\ \text{Beam } 8'' \times 3'' = 3 \times \frac{3 \times 8 \times 8}{6} = 96$$

$$(c)\ \text{Beam } 8'' \times 4'' = 3 \times \frac{4 \times 8 \times 8}{6} = 128$$

$$(d)\ \text{Beam } 8'' \times 6'' = 3 \times \frac{6 \times 8 \times 8}{6} = 192$$

hence 64 : 96 : 128 : 192 :: 2 : 3 : 4 : 6

or the strength of each is proportionate to the breadth, the depth being constant. To show that strength varies as d^2, compare three beams respectively $4'' \times 2''$, $6'' \times 2''$, and $8'' \times 2''$, and let T, as before, = 3 tons.

Then, from formula $T\frac{bd^2}{6}$

$$(e)\ \text{Beam } 4'' \times 2'' = 3 \times \frac{2 \times 4 \times 4}{6} = 16$$

$$(f)\ \text{Beam } 6'' \times 2'' = 3 \times \frac{2 \times 6 \times 6}{6} = 36$$

$$(g)\ \text{Beam } 8'' \times 2'' = 3 \times \frac{2 \times 8 \times 8}{6} = 64$$

hence 16 : 36 : 64 :: 4^2 : 6^2 : 8^2

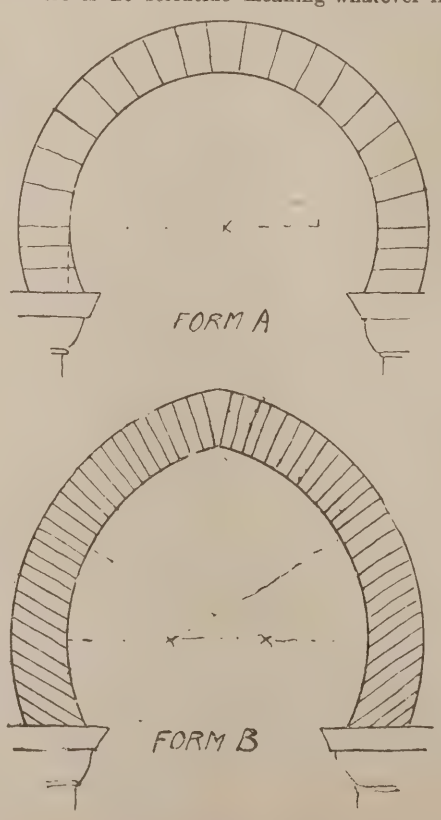
or the strength of each is proportionate to the square of the depth, the breadth being constant.

R. W. C.

Work in Borough Surveyor's Office.

SOUTH SHIELDS.—A. B. writes: "I should be glad if you would tell me what are the duties of a junior in a borough surveyor's office. Would six years' experience in an architect's office qualify one for the post?"

The work of a borough surveyor's office relates to the construction of roads and sewers and occasionally of buildings, with the supervision of sanitary works. An assistant should be a neat draughtsman with some knowledge of land surveying and levelling, and as much practical acquaintance with building materials as possible. Six years' experience in an architect's office might qualify a man for such a post in proportion as his experience had led him into the kind of work mentioned.



G. H. B.

The Horse-shoe Arch.

NEWCASTLE-ON-TYNE. — STUDENT writes: "From a scientific point of view, what is the meaning of the horse-shoe arch in Moorish architecture—that is, in the continuation inwards of the semicircular form, below the centre, from which the arch is struck? For example, the semicircular arch is required to carry a weight at the haunch, the pointed arch at the apex: what office does the lower part of the horse-shoe arch perform, or is it an arbitrary, fancy, or symbolic form? The derivation of this arch does not appear to be in the 'Encyclopædia Britannica.'"

There is no scientific meaning whatever in the horse-shoe arch, whether pointed or semicircular, and in many examples where it has been employed by the Moors in Spain its voussoirs are so arranged as to be as unstable as it is possible for an arch to be. In form A the voussoirs below the line from which the arch is struck are horizontal, and thus with a good abutment the arch does not differ from a semicircular or stilted one so far as its static properties are concerned. In form B the voussoirs radiate from the apex down to a line forming an angle of about 30deg. with the horizontal line, and from this point down to the support they are all cut parallel, and are therefore free to slide outwards or "vise" at the haunches, at the same time depressing the apex.

R. W. C.

THE HORSE-SHOE ARCH.

Overhanging First Floors.

LONDON, W.—ANOTHER CONSTANT READER writes: "In the erection of a pair of cottages on clay soil it is proposed to carry the overhanging front by the first-floor joists, with a small joist under supported at each end and in the middle by piers. Would it be better to carry the front entirely by a rolled steel joist, the floor joists on the first floor being laid at right-angles to it? The walls are 9in. thick, ground and first floor. Could I use something lighter than brickwork and yet satisfy the local by-laws?"

If the local by-laws permit, the first-floor front may be of open timber work, lath and plastered inside and rough cast outside. The floor joists should run through from back to front, and may be reckoned upon to carry not more than one-half the weight of the wall. The rolled joist will carry the other half—or, say, 5 tons—and should be $6 \times 5 \times 25$lbs., or $8 \times 4 \times 19$lbs.

HENRY ADAMS.

The Enfield Post Office, now about to be disestablished, was Queen Elizabeth's palace. A portion of the centre and the south wing of the Tudor building still remains, and within there are richly ornamented ceilings, oak-panelled walls, and a massive chimney-piece on which are inscribed the letters "E R.," with the arms of England and France quartered.

Building By-laws in Crewe.—The "Lancet" states that a more or less acrimonious newspaper correspondence has lately been passing between an alderman of the borough of Crewe and the former medical officer of health. In his last annual report upon the sanitary condition of Crewe Dr. Meredith Young referred to the unsatisfactory manner in which some of the building by-laws were being carried out, upon which Alderman Briggs questioned the desirability of the medical officer of health interfering with the erection of new buildings or with the enforcement of the building by-laws. The particular by-law which Dr. Young was anxious to have more rigidly enforced referred to the concreting of the sites of dwelling-houses, and as Crewe is situated upon a bed of stiff clay it is surprising that any person should object to his recommendation. That a medical officer of health does not exceed his duty in calling attention to breaches of building by-laws is made clear in a communication to Dr. Young from Dr. Franklin Parsons, assistant medical officer to the Local Government Board, in which he says that By-law No. 10 in Model Series 4, requiring a concrete layer under floors of houses, is made under the powers of Section 157 (2) Public Health Act, 1875, as one "with respect to the foundations of new buildings for the purposes of health." Article 18 (5) of the Local Government Board General Order of March, 1891, with respect to the duties of the medical officer of health, prescribes that "he shall advise the sanitary authority on any question relating to health involved in the framing and subsequent working of such by-laws and regulations as they may have power to make." Clearly, therefore, says Dr. Parsons, a medical officer of health has the right to call attention (of course in temperate and judicious language) to conditions injurious or dangerous to health which are allowed to come into existence owing to failure to carry out the by-laws.

Bricks and Mortar.

APHORISM FOR THE WEEK.

He who builds clears his purse.—ITALIAN PROVERB.

Our Plates. THE Casine, Clontarf, Dublin, was erected on an excellent site towards the latter part of the last century as a residence for Lord Charlemont. Its proportions and beautiful enrichments stamp it at once as a prominent example of the style with which the name of Sir William Chambers is indelibly connected. It is perfectly symmetrical on plan, and the effect of its general grouping becomes more pleasing by the simplicity employed in its construction. The detail of the particular order employed is somewhat richer than any example given by Chambers in his work on the five orders, and the details generally, from the principal entablature to the handles on the doors, bear strong evidence of the work of a skilful and clever designer. The measured drawings of the building which we publish gained for Mr. Henry J. Lyons this year the Travelling Studentship (value £10) of the Architectural Association of Ireland.

Professor Legros. PROFESSOR ALPHONSE LEGROS, the famous ex-Slade Professor of Fine Art at University College, is at present making a large fountain for the Duke of Portland. Professor Legros remains what he was when he first came to London, nearly forty years ago—a Frenchman pure and simple. Although his children speak English like natives, and without a trace of foreign accent—for they were born in London—he himself resolutely declines to use any other than his native language. At the time when he was Professor at University College all his criticism and teaching were done in French, with his assistant as interpreter. Although he is now sixty-three years of age, and his beard is quite grey, M. Legros has the vivacity of a young man.

A Famous House for Sale. THE sale is announced of the Charmettes at Annecy, a house famous in the annals of literature. It was here, as every reader of the "Confessions" knows, that Jean-Jacques Rousseau came as a youth after escaping from the harsh and tyrannical apprenticeship of M. Ducommun. It was here, says the "Daily Chronicle," that he met with Mme. de Warens, under whose roof he lived, and who, as he says, affected the whole course of his life. The Charmettes remain almost exactly in the same state as when Rousseau lodged there. At Ferney the relics of Voltaire are carefully preserved. In Chelsea the home of our own great philosopher has become a public possession. It may be hoped that the same respect will be shown for the little house to which Rousseau, in the course of his strange and chequered life, always looked back with fond recollection.

Truro Cathedral. IN a letter to the "Times" with reference to this Cathedral Mr. Mount-Edgcumbe says: "After the death of Archbishop Benson a movement was set on foot to complete the nave of the Cathedral which, as first Bishop of Truro, he had founded; and in 1898, having nearly £30,000 in hand, the committee, after much consideration, determined to remove the great temporary wall which closed in the western end of the previous work and to build the nave and west front. The work has progressed with almost unexpected rapidity, and is being admirably done; but how far it can be completed has to be determined almost immediately. Two alternative contracts were entered into—one carrying the western towers up to the eaves of the aisles, the other up to the eaves of the nave. The difference of cost between the two is £3,200, and we still require £2,500 to complete the lesser scheme, including all charges, or £5,700 to complete the whole. But the difference between the two schemes themselves is very great. If the committee is obliged to abandon the larger one (and, as I have said, the question demands an almost immediate decision), there will have to be more temporary walling, involving a waste of £400 or £500, and rendering the exterior unsightly for many years to come. On the resumption of work new scaffolding will also have to be erected at further cost within the building. If, however, we can now obtain sufficient promises of help to justify us in going on with the larger contract, not only will that waste of money be avoided and the external appearance much improved, but, what is more important, the interior will be thoroughly and finally completed."

The Home of the South Sea Bubble. THE historic South Sea House in Threadneedle Street (which dates back to 1773) is being pulled down to make way for a block of new buildings. Readers of Charles Lamb will remember the essayist's description of the place with "its magnificent portals ever gaping wide and disclosing to view a grave court with cloisters and pillars, with few or no traces of goers-in or comers-out—a desolation something like Balclutha's." The great house, however, has changed since Charles Lamb's time. He could speak of oaken wainscots hung with pictures of deceased governors and subgovernors, Queen Anne, and the two first monarchs of the Brunswick dynasty, of huge charts which subsequent discoveries had antiquated, dusty maps of Mexico "dim as dreams," soundings of the Bay of Panama, and pieces-of-eight long since dissipated or scattered into air "at the blast of the breaking of that famous bubble." Not only the pieces-of-eight, but most of the other relics, had vanished long before this last scene in the eventful career of the South Sea House. There was a sale of the furniture and fittings the other day, but most of the articles were quite modern and useful.

Lighthouse Building. A SPLENDID piece of work has been completed at the Foreland, in the Bristol Channel, near Lynmouth, in the erection by the Trinity Board of a much-needed substantial lighthouse, whose beneficent light will be appreciated by all whose duty it is to navigate the Channel. The contractors were Messrs. Jones Brothers, of Lynton, and both they and the engineer-in-chief (Mr. T. Matthews, C.E.) have had extraordinary difficulties in erecting the lighthouse and in making access to it, owing to the almost inaccessible position and the nature of the ground on which to build. The lighthouse buildings consist of dwellings for the principal keeper and assistant keeper, each of whom has a kitchen, parlour, three bedrooms, besides wash-house, &c., and an inspector's living room and bedroom, which will be used occasionally.

Walsall Municipal Buildings Competition. ON page 180 of our issue for October 3rd the recommendations of the assessor (Mr. J. Macvicar Anderson, F.R.I.B.A.) and the General Purposes Committee were published. At the meeting of the Walsall Town Council on October 8th the Committee brought forward their recommendation of Mr. J. Glenn Gibson's design, subject to its being found possible to carry out the work for a sum not exceeding the estimate of £55 000 by more than 5 per cent. They had directed, as agreed, that a premium of £100 should be paid to the five competitors placed highest in order of merit. The Mayor, in proposing this, said the Council had now reached a stage when a most important step in regard to the provision of municipal buildings had to be taken. The competition had been taken part in by ninety-four architects, and both the Special Sub-Committee and the General Purposes Committee were unanimous in approving the design now recommended. In addition to a town hall, there would be municipal offices, which it was hoped would meet the needs of the future, and which were no more than was necessary to enable the borough officials to cope with their ever-increasing work. The new buildings were only such as befitted the size and importance of the town, to which they would add dignity. Alderman Clare seconded the resolution, and Mr. Hughes, in supporting, expressed the opinion that the needs of the town would be met for the next fifty years. The recommendation was agreed to *nem. con.*

L'EGLISE STE. PIERRE, LOUVAIN. DRAWN BY A. M. PEART.

Ste Pierre, Louvain. THE drawing of the Church of Ste. Pierre which we print on this page was made by Mr. A. M. Peart whilst on Mr. Middleton's tour in Belgium last Easter. The date of the erection of the building is 1433.

THE PRACTICAL EDUCATION OF THE ARCHITECT.*

By Frederick Batchelor, F.R.I.B.A.

When Mr. Charles Darwin published his "Origin of Species" he was probably unaware of the extent of the debt under which he had laid us. The "unco' guid" then, as now, held up their hands. Like the Tories of a couple of thousand years ago, they had their doubts as to whether any good thing could come out of Nazareth.

The gift was accepted in principle, if not in fullest application, and apologists as far apart as the poles have adopted the methods which would derive the ape from the amœba, if not the local "A.A." from the nebula of Laplace. That about three years ago the "A.A." microcosm was in a nebulous condition, and that in some mysterious manner tides and eddies arose amidst the chaos and differentiated the nucleus of our little asteroid is already a matter of

London Street Architecture.

Irish history, and indeed our Presidential Addresses have followed a very similar course of development. Far be it from me even to hint that the opening address, *par excellence*, was at all of a chaotic character. Rather would I describe it as a brilliant *pot-pourri*, of necessity discursive, but pregnant of suggestion, as became the environment. A year later, when we were beginning to feel our feet under us, a pæan was sounded, a polemic on centralisation and registration which dragged the coat-tails of business and common-sense before the embryonic architects. This was duly followed by a panegyric which piped pleasantly of deeds, aims, and intentions—what might be termed, in publishers' journalese, a valuable Monograph on the Morphology of the Association.

Having in three successive sessions had the privilege of listening to a *pot-pourri*, a polemic and a panegyric, we are now ripe, if not for a pandect on decentralisation, for some measure of it at least in a plea for an improved general and technical education which will exploit its bearing on the survival of the fittest in the profession in which we all would excel.

The advantages of general education and culture are called in question only by those who are wanting in them, but their influence on professional success is not perhaps so universally or so fully appreciated as one could wish.

The advantages of a general education to an architect are intensified by two things: namely, the more technical character that is gradually being given to it, and the catholicity of an architect's profession.

Wherever civilised man is found, be he Christian, "Jew, Turk, Infidel, or Heretick," he loves to make his homes, institutions, palaces, and temples, not only cunning in contrivance, but each in its own way a little world of his aims and aspirations, a very Walhalla of all that is precious in art past and present, and to have impressed on each, and by a master hand, those individual, tribal and national characteristics which find more lasting if less vivid expression in architecture than the other fine arts. The designer has simultaneously to contrive, adorn and to find material expression in his work for the innermost habits and needs of every kind of client. The past may perhaps be peerless in monumental art, but I venture to think that nowhere has the range of a designer's sympathy had to be more catholic and encyclopædic than in the beautiful and loving domestic work which has marked this half-century's renaissance of architecture and its allied arts and crafts. When the tendency to the introduction of hand-and-eye training into most schemes of general education since the principles of Froebel and Slöjd have been abroad is considered, it will be abundantly evident that not only has the architect's need for general education and culture advanced, but that the theory of the latter has developed on lines perhaps more akin to the calling of the architect than any other, except those of the sculptor and painter.

There can be no doubt that a sound course of general education must precede any special departure, but how soon that departure is to be introduced into the home, school, or university is a misleading question. It assumes that there is but one answer, whereas there are as many answers as there are characters and callings. The Association has already done much, but I propose with your help to organise in the coming session a

Regular Series of Technical Demonstrations,

both at works in progress and also in the workshop. A pupil may know the four volumes of Rivington's "Building Construction" by heart, and have visited all the works on which the staff in his office are engaged, and yet be unfit to supervise, for three reasons: firstly, that every class of work does not necessarily find a place in the practice of even a very busy architect during the pupil's *quinquennium*; secondly, that a set of contractors has occasionally been known to do such good work as to deprive the pupils of their legitimate experience through rejection; and, thirdly, that visits to workshops and manufactories are quite as important as those to works in progress. I propose to meet the first want by arrangements such as have already been made with various architects and, occasionally, engineers to visit works in progress under their supervision. I do not anticipate insuperable difficulty in meeting the second want, but what we have yet to provide is a systematic series of demonstrations of good and bad materials and workmanship, and the means of distinguishing and appraising them, at sight and by applied test, taken, say, in the usual order of a specification. To meet the third want I look for the co-operation of the master-craftsmen, merchants and manufacturers in the neighbourhood of Dublin.

The timber trades alone will entail several pilgrimages. I question whether the most didactic among us would care to speak *ex cathedrâ* on the article itself. The stereotyped specification founded on the relations at one time rife between qualities, uses, ports of shipment, and market forms and marks is out of date, and the dearth of the dry red deals which stocked Dublin sheds in the good old days has not only introduced a new cult—that of the American baulk—but largely increased the demand for second Quebecs; whilst departures such as Kauri and Oregon pines, sequoia, canary, maple, and cypress are courting attention and making new demands on technical demonstration. From the timber yards we might perhaps turn to the creosoting works, and fill a few pages with notes on the process, the pounds per cubic foot injected for various uses, the pressures applied, and the depths of penetration. A visit like this, where we could handle the stuff, compare a few sawn sections, and pump the showman for all we were worth, would teach us more than a dozen text-book descriptions. After such a pleasant diversion our attention should be ripe for the saw mills and the carpentry and joinery shops.

The variety of sawn scantling now imported, especially from the Baltic, renders the appreciation of market forms in the importer's yard less problematical than when it was more confined to the log and the baulk, but it is in the saw-mills perhaps that we have most to learn from technical demonstration. I imagine that one of the chief advantages of technical demonstration in the joinery shops to a Science and Art "pass" man would be the dispelling of his little illusions in regard to the present use of framed floors and tongued and grooved back-linings in cased frames. What a shock to discover that the girder and the binder have been ousted by the steel section; that the insinuating steel nail makes a better edged-joint than the time-honoured tongue; that the tenacious tusk-tenon, the darling of his prettily-shaded isometrical details, is practically confined to trimming; and that so great a man as Viollet-le-Duc would drive it even from that refuge. What is even more wanted, because of its comparative neglect in this branch of technical education, is a similar demonstration in the shop-fitting and cabinet-making crafts; crafts whose niceties are only worked out by the specialist who can get a fair price and escape the demoralisation of the cut-throat competition now being fostered by Government departments. I would conclude the series by an examination of some of the best examples of genuine old joinery and fittings in the last-century houses of Dublin, such as still linger in Henrietta Street, Rutland Square, Sackville Street, Kildare Street, or Ely

* Inaugural Address delivered before the Architectural Association of Ireland on October 9th, 1900.

Place; and of the old furniture in the Science and Art Museum, much of which might be measured and drawn with advantage. Few technical studies are so refining in their influence upon the design of architectural joinery as that of the good old furniture of the sixteenth, seventeenth, and eighteenth centuries, and there can be little doubt that the coarseness of the Gothic Revival was largely due to its neglect. Another series of demonstrations which would very materially increase our stock of practical knowledge may possibly be arranged in connection with stonemason's work. In these yards the various building stones in common use for constructional purposes, and also those employed in decoration and in sculpture, could be exhibited and, I hope, a number of valuable hints obtained from the master-mason's ripe experience as to what quarries have produced the stones best able to resist the disintegrating effects of our Irish climate. We would expect, too, that the flaws and defects peculiar to each description of stone would be pointed out. The methods of setting out the work and the subsequent operations of sawing, dressing, carving and polishing the stones would be demonstrated. Then again we have in Dublin quite exceptional opportunities for seeing in well-equipped workshops art metal work, constructional steelwork and foundry work in all stages of production. I venture to think that if the young architect would avail himself of the opportunities now held out to him to increase his stock of practical knowledge, that knowledge would react most beneficially, not only on the morality of the master smith, but on the pocket of his clients. He would no longer create designs, presumably for wrought-iron, which could be produced only at excessive cost in that material, or else in the form of a malleable casting which might deceive both architect and client alike.

In the details of plumber's work the average architectural student or assistant is lamentably ignorant. He is probably acquainted with the first principles of sanitary plumbing; he will not, for example, leave a soil-pipe without ventilation; he will arrange for the disconnection of the house drain from the sewer, and he may even provide for a proper current of air through the drains; but when questions are put to him by the ingenuous plumber concerning the laying-out of the hot-water circulating pipes or the connection of the W.C. trap with the soil-pipe, he is liable to be placed in a position not entirely compatible with the dignity of the "arkos tectone."

From plumbing work it is not a far cry, in Dublin at all events, to enter the establishments of the master painters, for in more than one instance these trades, curiously enough, are combined.

Pilgrimages of similar scope, to the haunts of all the crafts that an architect calls to his aid, in ecclesiastical, civil, or domestic work, are in contemplation.

I have tried to put before you the paramount need of general education, of improved opportunities in the technical training which is our special stock-in-trade, and of the culture which refines their use and combines them to their best ends. Without a full measure of these things ambition is heavily handicapped. I speak, of course, of ambition in its broadest sense, the ambition to deserve and fill a niche in the Temple of Fame, not the mere instinct of self-preservation and successful plunder which we share with the domestic animal or the beast of prey; the desire to swell the store of wisdom already laid up in technical achievement and record, to raise and maintain the status of our calling, to extend without fear or favour the benefits of our ripe experience, to bear with and live down the prejudices or jealousies of our clients or fellows, and to feel ourselves efficient factors in private, social, and national life—citizens, in fact, of no mean city.

I have not spoken of personal gifts, but without a fair heritage of aptitude, fostered in the hope of something better than by-ends, the seed may fall on barren soil. If we cannot choose we can at least cherish them, so that when our barns and armouries are fuller than those of the less gifted or thrifty, we can draw upon ripened grain, or take down a burnished weapon from the rack.

I have pointed out that we have much to enlist both gratitude and hope in the new department, sop though it be, and I have suggested the ultimate establishment of a vastly more far-reaching scheme of State aid. Charles Lamb has shown us that to look a gift-horse in the mouth is a virtue rather than a vice, and thus is especially true of State aid. Those who run the State have, in addition to their ingrained aptitude for muddling, and the utter want of anything like business capacity in their nominees—have a pretty habit, especially in dispensing political charity, of undoing with the left hand what they do with the right. It may be a mistaken interpretation of the Divine injunction: "Let not thy left hand know what thy right hand doeth," but it is certainly neither business nor charity to set up a standard with one hand and besmirch it with the other! And yet this is what an enlightened Government is doing in the matter of technical education.

It is good for reflection to see, on the one hand, the feverish and belated efforts to provide the technical education which will place the failing artisan on equal terms with his better-taught German or American neighbour; and, on the other, the degradation of both master and man, on which year by year the Government is putting heavier premiums. I have already drawn attention to the inevitable result of cut-throat competition on the conscientious work that alone can train artisans worthy of the honourable name.

How is the master-craftsman to get a living price when strikes and the incapacity bred of the Government demand for jerry-work gnaw at one end of his profit, and indiscriminate calls for competition at the other, except by yielding to the temptation, mercilessly held out, of privity in the fraud? It is the knowledge that the degeneration which has followed in the wake of all the crafts that are prone to this evil—namely, those that are commonplace rather than *de luxe*—dates from the introduction, and thrives under the curse, of competition; it is this knowledge, I say, that has often induced concerns run on business lines to eschew competition and to act as notably the Belfast Banking Company did some years ago when they asked their architect, Mr. W. H. Lynn, R.H.A., to select the best contractor he could get for their new bank in College Green and settle a fair price. They knew that it was folly to put supervision to the test of getting what Mr. Ruskin has very properly termed "loving work" out of the signatories to the lowest tender, or to expect culture enough in a casual jury, possibly content with railway-station standards, to uphold the condemnation of work not obtrusively moribund or coarse; and they acted on their knowledge, with the result that the building is an object-lesson in material and workmanship.

I believe that this is the real plague-spot in our system, and that it behoves every good citizen who has the progress of technical education in Ireland and the Empire at heart to lend his influence to root it out, and render it less increasingly difficult to find what should never be divorced; namely, conscience and skill in the worker.

LONDON STREET ARCHITECTURE.

LONDON STREET ARCHITECTURE

WE print this week three drawings of London street architecture, by Mr. Sydney Newcombe; they are the first of a series of similar drawings which we propose to publish from time to time.

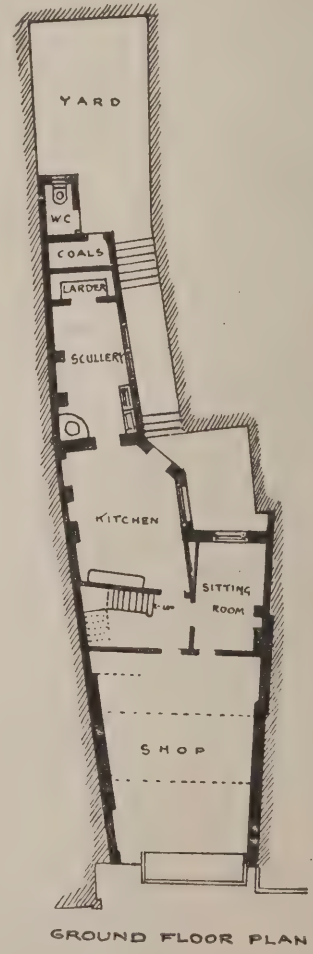
No. 60 Cheapside (see p. 201) is carried out in red gauged brickwork with Portland stone dressings, with the exception of ground-floor front, which is in polished granite. It was designed by Mr. H. Huntley Gordon, whose refined detail is such a relief to the mediocre architecture of many of our principal streets.

No. 1 Little Dean's Yard, Westminster, designed by Mr. T. G. Jackson, R.A., is used as a boarding-house in connection with Westminster School; it was described in our issue for June 30th, 1897, when we gave a reproduction of the elevation to courtyard. The front, shown

in the sketch on page 214, is built in yellow stock bricks relieved with red arches and jambs, with Portland stone sparingly used. Although this design has evidently been prepared with a view to economy, it is well worth inspection.

"The Yellow House" stands in the Bayswater Road, opposite the entrance to Kensington Gardens, and was designed by Messrs. Ernest George and Peto. It is carried out in yellow terra-cotta, the roofs being covered with green slates. The spacious forecourt is tiled and contains a sundial, giving the building an air of repose which is particularly noticeable in a thoroughfare possessing so many evidences of rush and bustle.

Professional Practice.



Brisbane, Queensland, Australia. — New General post-office and telegraph buildings are to be erected, and a competition for designs was recently held. The first premiated design was by Mr. John Barr, whose aim has been to keep each department distinct, with good lighting and cross-ventilation. The style is Free Classic. The walls are to be built partly of local sandstone and partly of brick with stone dressings. All partition walls are to be of terra-cotta lumber built in cement. Monier fireproof flooring will be used throughout. The public-hall floor is to be covered with large marble mosaic, the mail-branch floor with wood blocks, and basement and balcony floors with asphalt. The ceilings to the administrative branch are to be of plaster, and remaining ceilings of small corrugated iron; remaining floors of 4 by 1½ T. and G. boarding laid on battens. The heating is to be by electrical radiators in the rooms. On the ground floor an arcade is provided connecting Queen and Elizabeth streets, flanked by new lane, giving access to registration office, public lobby of money orders, stamps, telegraph, main staircase, clerks' entrance, private boxes, stores, parcels and dead-letter offices. First floor (17ft. high) has four departments on it, which have been arranged around a large central area. The administrative and money-order branches are arranged around three sides of an air court, which will be constructed as a balcony, having an asphalt floor with roofs over; doors from corridor and rooms will open on to it, and may be thrown open during hot weather. The central portion of this area is taken up by lantern lights to despatch-room. A service staircase is provided connecting all departments with pay clerks. Weather bureau and telephone exchange, 28ft. 6in. high, are placed at the Elizabeth Street end of the air court. The second floor (17ft. high) is taken up by telegraph and engineer's branches, the two departments being kept distinct, caretaker's or chief messenger's house being placed in centre of court over superintendent of money orders and lavatory. The telegraph room (34ft. high) has been provided with a gallery, with stores opening from it, having circular galvanised iron ceiling, and lighted by side and dormer windows. The basement floor (11ft. 6in. high) is basement to Queen Street and ground floor at Elizabeth Street, allowing parcels and dead-letter offices to be entered from arcade and street, thereby saving handling of heavy parcels, a loading space being provided at side. The estimated cost is £150,653. Messrs. Hall and Dod's design secured second place.

Driffield.—The new parish church, upon the site of the old one, has just been consecrated. It is of Romanesque type, with round arches and round-headed windows, and is faced inside and out with Lincolnshire bricks. The plan consists of nave, chancel, transepts, with short aisles, chancel aisle, vestry, and west porch. The principal entrance door in the west porch has a carved tympanum over the lintel, and a bell gable is provided at the west end of the nave. The roofs have curved boarded ceilings, with planted moulds dividing them into panels, and are constructed entirely of redwood. The seats, screens, chancel fittings, and wall linings are of wainscot oak. The extreme length of the nave and chancel is 106ft., and the width across the nave and transept 54ft., inside measurement. Sitting accommodation is provided for about 420. It is heated with hot water on the low-pressure system. Messrs. Hicks and Charlewood, of Newcastle-on-Tyne, are the architects, and Messrs. W. Leason and Son, Driffield, the sole contractors. The fabric has cost about £4,000. The pulpit and lectern are of carved oak. The roof is covered with red tiles.

Ilfracombe.—The building, No. 118 High Street, of which a plan and a front view are given on this and the next page, has lately been erected for Mr. J. H. Smith, butcher, at a cost of £1,100. The front is of Lawrance's T.L.B. red bricks with Bath stone dressings and carvings in Portland stone. The ground floor is laid with Duffy's Patent Acme Flooring, and the walls of shop are lined with white glazed brick. The architect was Mr. Allen T. Hussell, M.S.A., and the contractors were Messrs. Britton and Pickett, all of Ilfracombe.

Leeds.—Two new Board schools have recently been opened by the Leeds School Board, both schools being erected from plans by Mr. W. S. Braithwaite, architect to the Board. The new school erected in Stanningley Road, near Armley Park, occupies 5,052 yards of ground, and has been built to accommodate 1,180 children. On the ground floor, which is set apart for the education of infants, there is room for 410 children; and in the mixed department, on the first floor, which comprises a large central hall and twelve classrooms, there is accommodation for 780 scholars. The ground floor comprises a large hall and six classrooms, two of which are to be set apart for the care of babies. The heating apparatus, which has caused trouble in other similar erections, has been specially attended to. Large playgrounds adjoin the buildings. Inclusive of site and fittings, the school has cost £19,400.—The new school erected in Broad Lane, Bramley, has cost £10,016, inclusive of the site (2,665 square yards) and the fittings. It is a two-storeyed building, with accommodation for 650 children. The infants' department is on the ground floor, and consists of a central hall and four classrooms. Three of the rooms accommodate 60 each, and there is a babies' room. The mixed department, on the upper floor, has a central hall and six classrooms, each accommodating 60 children. The staircases are fireproof, and there are ample cloakrooms, teachers' rooms, &c., whilst at the rear of the building a workshop has been erected wherein at each lesson 24 boys may be given manual training. The heating is effected on the low-pressure hot-water system, and the ventilation has been carefully attended to. There are large playgrounds. The various contractors were:—Messrs. Appleyard Brothers, masons, &c.; Messrs. Trickett and Sons, joiners; Messrs. Sowry and Martin, plumbers; Mr. S. McFarlane, concreter; Mr. A. Marsden, plasterer; Messrs. Taylor and Parsons, ironwork; Messrs. Pickles Brothers, slating; Mr J. A. Naylor, painting; Messrs. Illingworth, Ingham & Co., furnishing.

Leicester.—The new Isolation Hospital has recently been formally opened, but there is still a good deal of work to do before the buildings leave the contractors' hands. The Town Council originally voted a sum of £54,000 for the buildings, but it is probable that the ultimate cost will exceed that amount. The designs of Messrs. Blackwell and Thomson, architects, of Leicester, gained the first award in the competition which the committee promoted, and from these designs the hospital has been built, Mr. Thomson having superintended the execution of the work. The site comprises about 14 acres of the Gilroes estate, and adjoins the Groby Road about a mile and a half from the Clock Tower. The administration block, a large two-storey building, faces the road at a short distance from the entrance. The hospital proper consists of four separate one-storeyed pavilions for the treatment of scarlet fever, giving accommodation for 26 beds each; a similar pavilion for typhoid fever containing 28 beds; two isolation pavilions—one a two-storey building—containing 28 beds, making accommodation for 160 adult patients. The buildings on the site have been so arranged that two additional scarlet fever pavilions can be easily added, and one additional isolation pavilion. It is suggested that the separate rooms in the isolation blocks can be conveniently used for typhoid patients should occasion require, hence an additional typhoid block is not projected. The other buildings comprise the administration block, discharging block, and mortuary, engine and boiler house, laundry, and porter's lodge. The total number of beds, if the full extension were carried out, would be 240. The several buildings are connected by macadam roads without covered ways, the ambulance vans thus being able to drive up to the door of each block. Owing to the natural fall of the ground, north to south, terracing is being adopted to some extent, the earth removed from the higher parts being used to fill up the lower portions as terraces, thus avoiding a large amount of unnecessary brickwork below the ground floor line. The site has an average elevation of about 280 feet above ordnance datum. The four scarlet fever pavilions are all arranged alike, and consist of two main wards, 72 feet long and 26 feet wide, to contain 12 beds each. In the central portion is provided a separation or observation ward of two beds leading out of the ward corridor, and having its own lavatory and w.c. The nurses' kitchen is centrally placed, and can overlook the beds in the two main wards by means of observation windows. At the distal end of each main ward is placed on one side the sanitary tower, containing the w.c.'s, slop and scalding sinks, disconnected by a ventilated lobby, and on the other side the bath-room, which contains two baths and two lavatories. The typhoid pavilion is very similar in plan to the scarlet fever pavilions, except, as the block will be used for two sexes, it is necessary to provide two separation wards instead of one, as in the scarlet fever blocks. The one-storey isolation block provides for a total of 12 beds. The two-storey pavilion is arranged on two floors, one half to face east, the other half west. On both floors in each half two two-bed wards are provided, leading on to the verandah, with nurses' kitchen and larder. The sanitary towers are approached from the verandahs. The first floor in each

GROUND FLOOR PLAN

PREMISES NO. 118 HIGH STREET, ILFRACOMBE.

half is approached by an open stone staircase at the extreme end of the verandahs. The floors of the wards are constructed of teak blocks. The administrative block contains on the right of the front main entrance, committee-room, doctor's sitting-room, lavatory, etc., dispensary, laboratory sto e, waiting-room and telephone enclosure; and on the left of the entrance, matron's sitting-room, office, nurses' mess-room, sitting-room, sewing-room, household-linen room, dry goods store, lavatory, etc., servants' hall. The servants' hall and nurses' mess-room are placed in close proximity to the kitchen. The floors of the corridors, kitchens, etc., are of terazzio. The first floor contains the nurses' and matrons' bedrooms, with bath-rooms, w.c.'s, and linen store. The doctor's bedroom and bath-room are also on this floor, and are approached by a separate staircase. Twenty bedrooms for nurses are provided on this floor. The second floor contains ten bedrooms for servants, a bath-room, etc. The porter's lodge is situated on the right-hand side of the main entrance from Groby Road, and stands 15 feet back. At the rear of the porter's lodge, on the right-hand side of the entrance roadway, is the discharging block, which is arranged in duplicate for male and female patients. A mortuary is of necessity provided, consisting of a post-mortem room, mortuary, and viewing chamber. The heating throughout is by low-pressure steam, with auxiliary heating arrangements consisting of stoves and grates. The sewage from the drains from the scarlet fever pavilions, typhoid pavilion, isolation block, and administrative block is each kept quite distinct, and is pumped up into one of the main carriers on the sewage farm by means of a Shones' ejector apparatus. The facings to all the buildings are Ellistown brick, with stone dressings, and the roofs are covered with green slates. The hospital is lighted by electricity throughout. The building has been carried out by Mr. J. F. Johnson, of Leicester, and the plumbing, etc., by Mr. F. W. Haskard, of Halford Street, Leicester.

Longforgan, Dundee.—Longforgan Church has just been undergoing alterations. The whole of the old pews and flooring, together with the old gallery which encircled on three sides the pupit, have been entirely removed. The old internal stone stairs giving access to either end of the gallery have also been removed, thus throwing open the whole internal area of the church for fresh treatment. An eastern annexe or chancel having a Gothic window of three lights to the east has been erected, communicating by means of a wide semicircular archway in the east gable of the old church. The structure has been refitted with new joists and flooring, and reseated with new pews of pitch pine. A small gallery runs across the west end. A vestry has been erected to the south of the chancel, while an exit porch has been provided in the corresponding angle at the north. The pulpit, which is octagonal in form, and of ornate design in cypress wood, occupies a site near the south spring of the chancel arch. It is fitted with carved panels. The three-light opening in east wall of chancel has been filled in with a series of stained-glass memorial windows, illustrating the Ascension. The walls of the church have been tinted. The church has been heated by coils of pipes on the low-pressure system. Mr. A. Hutcheson, of Dundee, is the architect, and the contractors for the various departments of work were: Mason, Robert Goodall, Errol; joiners, D. W. Clarke and Son, Dundee; plumber, A. L. Peacock and Co., Dundee; slater, James Laburn and Son; plasterer, James Laburn, Dundee; heating, G. H. Nicol and Co., Dundee; painting, William Norwell; glazing, Lindsay and Scott; sculptor, Alex. Neilson, Dundee. Messrs. Clayton and Bell, London, supplied the chancel window and carried out the decoration of the chancel.

Twickenham.—New business premises are about to be erected in York Street, from the designs of Mr. Paul Hoffmann, architect, of 152 and 153 Palmerston Buildings, Old Broad Street, E.C. The one will be known as "Victoria House," and will occupy a very prominent posi ion at the angle of York Street and

PREMISES, NO. 118 HIGH STREET, ILFRACOMBE. ALLEN T. HUSSELL, ARCHITECT.

Richmond Road, and the other opposite. These buildings, as well as several others in the same street, the designs of which have been entrusted to the same architect, will be erected in red brick and Bath stone. Some of the proposed new shops will have the usual living and bedroom accommodation on the upper storeys, while the upper portions of "Victoria House" will be occupied by residential flats, the bedrooms of which will overlook the grounds of York House. The contractor is Mr. T. W. Brown, of Hornsey and Bexhill-on-Sea, where he has just completed a block of shops and flats known as "Marina Court," for the designs of which Mr. Hoffmann has also been responsible.

GRANITE PAVING.

BY CHARLES T. RUTHEN, C.E.

GRANITE paving, when properly laid, will outlast any other form of roadway, more especially when subjected to very heavy wear. Its chief objection is that it is naturally very noisy; but this defect does not appear to have affected its general use upon roadways over which heavy merchandise is conveyed. Cost of maintenance is a great deal less than with ordinary macadamised roadways, and needless to say it is exceptionally clean compared with a macadamised road. The latter point alone is a very serious question in a large town.

North Wales granite setts are considered very good for use on roads used for heavy traffic, and are of course the most economical for ordinary traffic: but the cost is slightly more than that of Irish and other granites.

Construction.

The following description of the method of construction will give a fair idea:—If the roadway is an old one, the excavation would be taken out to the depth required for the foundation and setts, say a minimum of 12in. The bottom of the foundation would be parallel with the finished surface line of the setts. The foundation should be a bed of concrete at least 6in. thick (covering the whole of the portion to be paved), composed as follows, namely, six parts of screened ballast or gravel (all of which will pass through a screen of 2½-in. mesh) and one part of Portland cement, all thoroughly mixed upon a platform and used while in a semi-liquid state. Concrete made with lime instead of cement is equally good and very much cheaper. The proportions would be the same if lime were substituted for cement.

The lime should be ground blue lias, Aberthaw, or other similar lime, and seived through a screen of 2,500 meshes to the square inch. The cost of ground lime as above is about one-half that of cement. If the old material on the road be ordinary metalling, this will, after being screened, make a proportion of the concrete, instead of using ballast or gravel.

It would be well to note that the depth of the foundation varies according to the nature of the ground, and would be all the better by being 9in. or even 12in. deep instead of 6in. Should the ground be very soft, the roadway would be improved by the addition of a bed of stones, say 12in. deep, laid under the concrete foundation.

Some Things to Remember.

One ton of cement equals exactly one cubic yard, and, when mixed in the proportions of six to one, the resultant mixture is about seven cubic yards of concrete. This will cover an area of 42 superficial yards 6in. deep.

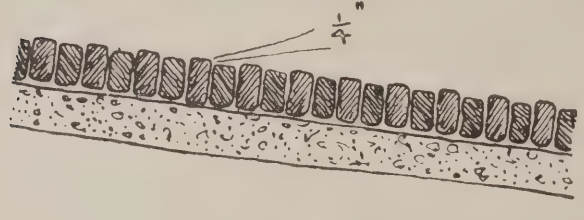
One ton of ground lime mixed in the proportion of six to one will cover 50 superficial yards 6in. deep. Fourteen labourers, mixing and laying concrete, will complete about 135 superficial yards per day.

As the concrete foundation is laid, the surface is well rammed with large flat rammers, in order that the concrete may get thoroughly consolidated, and so that the top surface may be brought to a fairly smooth face. The curvature of the concrete bed must be the same as that which is intended for the finished road-surface of the paving. The concrete foundation should have at least forty-eight hours to set before the paviors commence their work.

A bed of sand, 1in. in depth, is spread over the concrete foundation when ready for the setts. This sand acts as a bed for the stones. The size of granite setts varies. Those frequently used are 7in. by 5in., 5in. by 3in., 6in. by 4in. Paviors will lay an average of about 27 superficial yards each per day of nine hours.

After the stones are laid they are well rammed with heavy rammers, in order that they shall have a good solid bed, after which gravel (nothing smaller than ¼in. and nothing larger than ½in. gauge) is spread over the surface and brushed into the joints previous to the running of the grouting mixture. This process has the effect of wedging the stones and keeping them in place.

Grouting material composed of lime and sand or of cement and sand in equal proportions is often used, the mixture being made into a liquid state, spread over the surface of the roadway, and brushed into the joints.



Bituminous Mixture

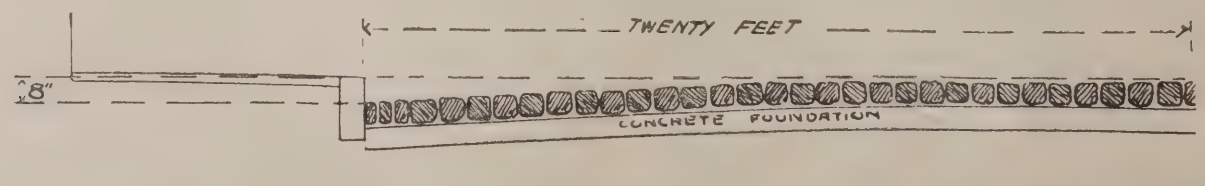
is, however, by far the best grouting material, and is composed of the following, namely, pitch and tar in the proportion of 2⅔gals. of tar to 1cwt. of pitch, thoroughly boiled in a special pitch boiler made for the purpose. These boilers vary in size, but there are two sizes in general use. The larger size holds 9cwt. of pitch and 24gals. of tar, and when boiled this makes about 150gals. of the mixture. The smaller size will hold just half this amount: 150gals. of this grouting mixture, as above, will flush the joints of about 22 superficial yards of paving. The quality and suitability of this mixture depends greatly upon the quality of the pitch and tar used. The proportions given above are for the best materials.

Pitch boilers can be "charged" four times a day—that is to say, with the large boiler 600gals. of bituminous grout could be prepared in one day, and with the smaller boiler about 300gals. The first "charge" takes about three hours to prepare, and the three subsequent "charges" two hours each. Three men grouting with the bituminous mixture will flush the joints of about 132 superficial yards of paving per day (with one large and one small boiler at work boiling the mixture).

After the grouting process has been completed, the surface of the road is covered with a thin coating of fine gravel, and at least seven days are allowed to elapse before traffic is permitted upon the road.

The approximate time required to pave a roadway with granite setts in the manner described may be gathered from the following figures, namely, 2,825 superficial yards may be completed in thirty whole working days, inclusive of excavation of old metalling or other material to the depth required for the new foundation, concreting, paving, and grouting; average number of men employed being sixty labourers and concretors, two rammers, three pitch runners, four paviors, one foreman and one ganger.

SKETCH A.



SKETCH B.

Inclines

exceeding 1 in 26 should not be paved with granite setts, although steeper gradients are paved in this manner; but considerable danger arises from the use of granite upon inclines greater than that mentioned.

A small projection, say of ¼in., made in each course when the stones are being laid (see sketch A) upon steep hills, will be found to be a great improvement, and safer for vehicular traffic (the projection affording a foothold for the horses) than the ordinary method of paving, as laid upon practically level roads. Another method of dealing with this point is shown on sketch B, every alternate course being lowered.

The curvature of the surface is shown upon sketch C. This varies according to the longitudinal gradient, but that shown upon sketch is very satisfactory for a level or nearly level road. If the cross gradient is too great, heavy vehicles, when using the roadway, gradually "slide" into the channel, and it is most difficult to get the vehicle on to the centre of the road again.

SKETCH C.

A Swiss Lady Architect.—The town of Mediasch (Switzerland) has chosen from a number of plans sent in for the new town hospital the design of Miss Erika Paulas. This lady is the daughter of an engineer, and was born in Zurich in 1875. As a child she displayed a great talent for drawing, and when quite a young girl surprised the town authorities of Bistritz (where her father held an appointment) by the design she sent in for new barracks. In the year 1895 she passed the usual builders' examination, and then all the examinations necessary to take an architect's degree.

LONDON COUNTY COUNCIL.

ON Tuesday in last week the Council met for the first time since the summer recess. In the course of his annual address Mr. W. H. Dickinson, the Chairman, said that whereas in the year 1898-9 the Council undertook works involving a gross capital expenditure of £7,000,000, it had in the year now under review practically involved itself in liability for a gross capital expenditure of more than £11,000,000. The chief items of that large sum in round figures were:—(1) New main sewers, costing about three millions (but of that only one and a half millions had been actually decided upon); (2) tunnel under the Thames, two millions; (3) improvements, three millions; (4) artisans' dwellings, one and a half millions; and (5) tramways and light railways, one and a half millions. The nett result of the Council's work during the eleven years of its existence as felt by the London ratepayer had been an addition to his rates in respect of debt of a sum of less than ½d. in the pound. Dealing with the housing of the Council's staff, the Chairman said that, in addition to the main building in which the Council sat and the three adjoining houses which had been added to it, they had no fewer than twenty distinct houses, many of which were a long way from the Council's headquarters. Turning to the

Main Drainage Work,

the Chairman said that the total amount of sewage treated in the year had been 79,382,570,830 gallons, and the weight of sludge sent to sea had been 2,288,000 tons. The most important act of the committee during the year had been to induce the Council to embark upon the great scheme of extension of the main drainage which was some time ago elaborated by Sir Alexander Binnie, and was estimated to cost £2,947,000. The existing system, laid down forty years ago, was designed to serve the needs of an anticipated population of 3,450,000 persons; but the growth of London had exceeded all expectations, and they found that already the population using their system exceeded 4,700,000, and the sewers now conveyed in dry weather 80 per cent. more sewage than the amount which they were constructed to carry. Under those circumstances the Council had, after very great hesitation, felt that the enlargement of the drainage system must be commenced, and on December 5th, 1899, it agreed to the recommendations of its committee. Those recommendations did not cover the whole field, as it was deemed advisable that only the new outfall sewers should at first be constructed. That work involved an expenditure of £1,250,000, or about two-fifths of the complete scheme.

The Improvements Committee had, the Chairman remarked, carried through reports involving a nett cost of £2,047,840 for sixteen schemes. As regards the parks and open spaces, whereas in 1889 the Council's parks and open spaces numbered 40, they now numbered 91. In the former year the annual maintenance of them cost £52,000. It had now increased to £114,000. Turning to the

Housing Question,

the Chairman said that, taking buildings either completed within the past twelve months or nearly completed, the money value of these amounted to £370,000, or three times as much as in any previous year. Beyond that they had over £350,000 worth of buildings ordered, but not then put out to contract, bringing the total value of buildings decided upon up to £720 000. In addition, they had building schemes not finally approved by the committee, but in a more or less forward state of preparation, of the value of £1 500,000. The total value of the work requiring attention was therefore not far short of two and a quarter millions, an expenditure which would impose no slight responsibility and burden upon the office of any architect. In return for that expenditure nearly 50,000 persons would be accommodated, bringing up to 59,751 the number of persons provided for since the inception of the Council in 1889.

On the subject of water the Chairman remarked that the average daily flow of the Thames in September over the period of seventeen years had been 491,500,000 gallons. When it was borne in mind that the Balfour Commission reported that London within thirty-one years from now would require to draw 300,000,000 gallons a day from the Thames, and that, in the opinion of that Commission, at least 200,000,000 gallons should be left at all times to flow down the river, it was clear not only that the amount of reservoir accommodation necessary for storing the winter floods in sufficient quantity to provide for summers like those of 1898 and 1899 would be far greater and far more costly than the Balfour Commission ever suspected, but also that in the end London would be compelled to resort to new sources at much greater expense than if that were undertaken now. He believed that if the present opportunity were lost, future generations would look back to their action with much the same feeling of regret as that which they had expressed at the action of the City of London when in 1612 it gave the control of the New River undertaking over into private hands. The Council passed a vote of thanks to the Chairman and ordered his address to be printed.

The Piccadilly Widening Scheme.

The Improvements Committee brought up their report, originally submitted on July 24th, in favour of making an arrangement with the Government for the widening of Piccadilly to about 170ft. between Hyde Park Corner and Walsingham House by cutting off a slice of the Green Park. The committee in their report impressed upon the Council the fact that Piccadilly was one of the main thoroughfares of London, and must, in their opinion, always remain so. It was frequently congested not by local, but by general through traffic. They considered that this traffic must continue to increase, and therefore it must be indeed plain that the widening of the thoroughfare at no distant date was inevitable. The present was a very favourable opportunity for securing the improvement at a most reasonable cost, and they were therefore strongly of opinion that the Council would do well to approve the proposal at once, and undertake to pay the cost of the necessary paving and other works. It might be desirable to make one or two very slight alterations in the line of widening shown upon the plan submitted, and they therefore proposed that the Council's undertaking to pay the cost of the works should be subject to the details of the plan being hereafter agreed between the Council and the Office of Works. They understood that the First Commissioner quite concurred in that course. They also stated that if, instead of acquiring vacant land, the Council had to arrange for the setting-back of the buildings on the northern side of Piccadilly, the cost would not be less than 1½ millions sterling. In the case of the widening of the Strand at the Hôtel Cecil, for which the Council arranged in 1896, the thoroughfare was widened to 80ft. for a length of only about 225ft.; but although in that case vacant land was acquired, and the Council did not have to pay for trade interests, the improvement cost the Council £30,000, which, in the circumstances, was rightly considered a reasonable sum. In the case of Piccadilly, however, the street would be widened for a length approaching half a mile at no greater cost than that of widening the Strand for a length of only 225ft., namely, £30,000, the Council having in the case of Piccadilly to pay nothing for the land. They recommended that the proposal should be accepted. After a short discussion the recommendation was agreed to.

The Building Act Committee reported that they had refused their consent, under sections 13 and 41 of the London Building Act, 1894, to the erection of fourteen shops, with rooms over, on a portion of the yard on the west side of Ludgate Hill Railway Station, and of a kiosk at the north end of such yard, abutting upon New Bridge Street and Pilgrim Street, as shown upon the plans submitted with the application of Mr. W. Wallace on behalf of the South-Eastern and Chatham Railway Company.

The Council decided to send a letter to the Local Government Board asking that it might be authorised under Clause (C) of the memorandum of association of the Sanitary Inspectors' Examination Board to appoint five representatives to serve on that Board, and stating that the Council would be glad if the president of the Board would receive a deputation from the Council in support of its request.

A YEAR'S BUILDING IN GLASGOW.

SIR JAMES BELL, Bart., whose term of office as Lord Dean of Guild has just expired, in his valedictory address recently at the Glasgow Dean of Guild Court, reviewed the work for the year ending August 31st last. He stated that the year closed had the fourth largest valuation. The demand for houses and shops seemed to have been very great up to the year 1897-98, but since then there was a steady decline of, roughly, nearly £300,000 per annum. Last year in valuation there was only about half that in 1897-98. Under the heading of public buildings this year showed an increase of from five to eight, but a fall in the money valuation of from £144,400 to £42 500. Churches, halls, and schools showed an increase in both numbers and valuation; twelve linings last year, with a valuation of £88,680, against fourteen linings this year, with a valuation of £106,050. A most gratifying feature of last season's work was the great increase in the valuation of warehouses, shops, and workshops, the number last year being 113, against 115 this year; while the money valuation increased from £516,490 last year to £757,870 this year, or an increase of little less than a quarter of a million. This increase was all the more striking because 1898-99 was the first year this exceeded the half-million. Additions and alterations to properties, while 104 fewer in number than the previous year, showed about £3,000 more in valuation, fully accounted for in the increased price of material and wages paid. During the past year 20 new streets were granted linings of 5,722 lineal yards. Taking the total number of linings granted last year, the numbers are 533, with a valuation of £1,900,428. Turning again to the heading of houses and shops, Queen's Park district showed the greatest activity in regard to building, the number of linings granted there being 32, with a valuation of £233,050. In this division only three houses were of one apartment, 107 of two apartments, 165 of three apartments, 98 of four apartments, 61 of five apartments, and 59 of six and upwards. The Eastern Division came next in the number of linings and valuation. The linings are 17 in number, with a valuation of £126 867; but on analysing the return, in the Eastern Division there were 132 of one apartment, 360 of two, 121 of three, and only 28 of four rooms and upwards. Maryhill Division came third in the list, with a valuation of £109,700 for 14 linings, that including 42 one-roomed houses, 161 two-roomed houses, 12 of three rooms, 22 of five, and 46 of six rooms and upwards. The St. Rollox Division, whilst fourth in the list, showed a very large number, a regrettably large number, of one-roomed houses. The linings were ten in number, with a valuation of £49,850. These covered 272 houses of one apartment, 412 of two apartments, 55 of three apartments, and only 6 of four rooms and upwards. In the Central Divison there were only two linings granted for shops and houses, with a valuation of £46 400. In the Western Division two, with a valuation of £44,000. In the Northern four, with a valuation of £39 500. A very large proportion under the columns marked additions and alterations, with a total of 298 linings and a valuation of £344,641, had been occasioned through the coming into force of the various Health Acts of the City of Glasgow.

A new Church at Dundee for St. Thomas's Established Church congregation is to be erected on a site at the junction of Lochee and Tullideph Roads. The cost of the building, which will accommodate 800 worshippers, will be about £5,000. The plans of the new building were prepared by Messrs. Johnston and Baxter, architects, Dundee.

Engineering Notes.

The New Hospital at Totnes is being warmed and ventilated by means of Shorland's patent Manchester grates, supplied by Messrs. E. H. Shorland and Brother, of Manchester.

"Hawthorpe," Uppermill, near Oldham.—This residence has lately been fitted with the improved hot-water heating apparatus by Messrs. John King, Ltd., engineers, of Liverpool, who are employing their ornamental "Rahnee" radiators.

Electric Tramways for Folkestone. — On Wednesday last the Folkestone Town Council decided to apply for Parliamentary powers to construct a system of electric tramways in Folkestone, at a cost of about £93,000. The scheme includes both the overhead and conduit systems.

Change of Address.—Messrs. H. J. Skelton and Co., engineers, iron and steelwork contractors, &c., have changed their address from 12 Lime Street, E.C., to 71 Finsbury Pavement (Electric Railway Station Buildings), Moorgate Street, E.C. The firm's new telephone number is 1692 London Wall.

New Thames Tunnel.—The scheme for the new tunnel under the Thames between Rotherhithe and Ratcliff is making progress. The Bridges Committee of the County Council estimate that it will cost £845,750 to acquire the property necessary for the scheme. The Council will be asked this month to authorise the expenditure.

Water Supply of Douglas, I.M.—Mr. F. Thorpe, of Greenfield, Oldham, has been appointed overseer of the new reservoir which the Douglas Corporation are about to construct in Baldwin Valley. The work will commence almost immediately. Mr. Hill, of Manchester, is the engineer of the undertaking, which will cost £50,000.

Chester Tramways. — The Chester Town Council resolved on Wednesday last to apply to Parliament for an Act empowering them to take over the Chester tramways undertaking, to adapt it for mechanical traction, and to extend the system beyond the borough boundaries. The price paid by the Council to the tramway company is £18,300, plus the value of the rolling stock.

The Watering of Tramways.—The National Cyclists Union has now taken counsel's opinion as to the legality of tramway companies watering their lines, and is advised that the excessive watering of the tramlines is a nuisance for which tramway authorities have no justification under their Act of Parliament. The National Cyclists Union is obtaining expert and other evidence upon which it hopes very shortly to commence a prosecution.

New Pier at Yarmouth.—The Widnes Foundry Company, of Widnes, are the contractors, and Messrs. Mayoh and Haley, of London, are the engineers for the new structure intended to take the place of the present antiquated pier at Yarmouth. It is proposed to make the pier 800ft. long; for half of that length the width will be 50ft. and the other half about 150ft. On the wider part there is to be a pavilion capable of holding 2,000 persons, and designed for concerts and theatrical performances. The pier will cost about £50,000.

Lambeth Bridge.—As the present bridge at Lambeth is in a very unsatisfactory condition, Sir Alexander Binnie has prepared plans for a suspension bridge, with an alternate design for a more rigid type of construction, technically known as the "braced-arch." The new bridge is to be wide enough for a double line of tramway, 66½ft. to 68ft, with a gradient of from about one in forty-one to one in thirty-four. As the bridge will be situated in the neighbourhood of the Houses of Parliament, and will lead to Lambeth Palace, it must in some way be made to harmonise with both. The Bridges Committee therefore propose that one of the best authorities on Gothic architecture of the day should be asked to advise in working out the details of the piers, towers, and abutments of the bridge.

New Bridge over the Tay.—On Saturday last Sir Robert Pullar, of Tayside, opened the new bridge over the Tay at Perth, which has cost £35,000.

King's College, London.—The £15 Engineering Entrance Scholarship has been awarded to Mr. N. G. Langrish, one £10 to Mr. J. H. P. Bilbrough, and the other £10 to Mr. F. R. Fairmaner.

Improvements at Antwerp.—It is proposed to extend the city of Antwerp and to construct several miles of quays along the Scheldt. The project, which has aroused much interest, includes the construction of a new industrial city on the left bank of the river, to be connected by a city tunnel.

Electric Light for Hornsey.—On Friday last a Local Government Board enquiry was held into the application of the Hornsey District Council for sanction to borrow £73,500 for electricity works. Mr. Robert Hammond, consulting electrical engineer to the Council, explained that the cost of the undertaking would be as follows:—Generating works, £28,110; feeders and distributors, £31,003; public lighting, £4,700; meters, house connections, &c., £4,575; and general charges, £5,112; making a total of £73,500.

New Electricity Works at Poplar, London, E., have been opened. They have cost about £100,000, and have been carried out under the supervision of Mr. Alfred Blackman, M.I.E.E. (formerly electrical engineer to the Aberdeen Corporation). The present total capacity of the station is 32,000 eight-candle power lamps, but space is left for large extensions. The arc lamps erected in the principal thoroughfares number 195, and it is proposed to convert 680 ordinary street lamps by fitting incandescent electric lights. It may be added that there are sixty-five miles of streets in the three parishes of Poplar, Bow and Bromley, and that more than thirty miles of mains have already been laid. Arrangements have been made with the National Electric Wiring Company for free installations for private consumers; and current will be supplied under the maximum demand system for lighting at 5d., 4d., and 3d. per unit (the prices being for the first, second, and following consecutive hours respectively), and for power at 3d. and 1½d. As the private company which desired to light the district proposed to make charges of 7d. per unit for lighting, and 5d. for power, the advantage of municipal lighting will be apparent; while as gas in the district costs 3s. per thousand (which is roughly equivalent to electric light at 6d. per unit) the new illuminant can compete with the older. Arrangements are being made for the supply of meters on the slot system. Already applications have been received for 5,000 eight-candle lamps, so that the enterprise may claim to be making a good start. It may be added that all the buildings at the works in Glaucus Street, Bromley, were erected by the direct employment of labour under the control of the Board's surveyor, Mr. Winter.

Surveying and Sanitary Notes.

A New System of Drainage at Eastbourne was recently carried out at a cost of nearly £100,000, and has just been viewed by a deputation from Nice.

The Surveyors' Institution.—An ordinary general meeting will be held on Friday, October 19th, at 3.45 p.m., for the special purpose of reading a balloting list (No. 25) for the election of new members, and a balloting list for the election of a new member of council to fill the vacancy caused by the death of Mr. William Wright, of Wollaton. The first ordinary general meeting of the session 1900-1901 will be held on Monday, November 12th, 1900, when the president, Mr. John Shaw, will deliver an opening address. The chair will be taken at 8 o'clock. The following members, having passed the requisite qualifying examination, have been transferred during the recess from the class of "Professional Associates" to that of "Fellows" of the Institution:—On June 27th, 1900: William Easter (King's Lynn, Norfolk), Thomas William Alfred Hayward (Sudbury, Suffolk), Fitz-Lawrence Percival Dudley Jennings (Bournemouth), Dyneley Luker (Ealing, W.), Percy Edward Ridley (London, S.W.), John Henry Shufflebotham (Taunton). On October 1st, 1900: Henry Hugh Addiscott (London, S.W.), Francis Julian Laurence Birch (Melplash, Dorset), Richard Herbert Chichester (Market Drayton), William Clarkson (Poplar, E.), George Crosbie Dawson (Nuneaton), Dugdale Oakeley Dunlop (Manchester), Howard Goadby (Twickenham), Arthur Ernest Hope (Forest Gate, W.), David Pugh Jones (Llandaff), William Beaumont Leather (Leeds), Douglas Samuel Matthews (London, S.W.), Richard Frederick Parry (Bishop's Waltham, Hants), James Reginald Pineger (London, W.), William Sly (Whitehaven), Charles Gordon Smith (Stamford Hill, N.), Charles Herbert Southorn (Leamington Spa), Frederick Beauchamp Wells (Lympsfield, Surrey). It has also been announced that the following, having passed one of the examinations exempting candidates from the preliminary examination of the Institution, have been enrolled by the Council:—As Students: Frederick Bartlett Lang (Plymouth), Hugh Francis Vivian Parrott (Hayes), Albert Priest (London, S.W.), Herbert Henry Wigley (Winslow, Bucks). *Students' Preliminary Examination*, 1901.—Those proposing to enter their names for the students' preliminary examination, to be held on the 16th and 17th of January next, must intimate their intention to the Secretary before the last day of November. It is proposed to examine candidates from the counties of Lancashire, Cheshire, Yorkshire, Durham, Cumberland, Westmoreland, and Northumberland, at Manchester. Candidates from other counties in England and Wales will be examined in London, Irish candidates in Dublin, and Scottish candidates in Glasgow. *Professional Examinations*, 1901.—The students' proficiency examination will commence on the 18th of March next. Examinations qualifying for the classes of Professional Associates and Fellows will also commence on the 18th of March next. All particulars as to days, subjects, and course of examination will be forwarded on application to the Secretary. English candidates for the professional examinations will be examined in London, Irish candidates in Dublin, and Scottish candidates in Glasgow. *Special-Certificate Examinations*, 1901 (for Members).—Notice is also given that the next special-certificate examinations in forestry and sanitary science will be held on Tuesday, Wednesday, and Thursday, the 11th, 12th, and 13th of June. Particulars of these examinations can be obtained from the secretary, 12 Great George Street, Westminster, S.W.

BUILDING TRADES' GIFT.

MR. T. F. RIDER, past-president National Association of Master Builders, as honorary secretary of the Building Trades' Gift to the Nation, announces the following further subscriptions:—

	£	s.	d.
THE BUILDERS' JOURNAL Shilling Fund (Subscriptions, first instalment)	57	12	0
Messrs. F. and H. F. Higgs and Workmen	10	0	0
Messrs. H. Stevens and Co. and Workmen, Southampton	6	17	2
Messrs. Harris and Wardrop and Workmen	5	15	3
Workmen of Messrs. James Carmichael, Wandsworth	3	15	3
Messrs. George Nutter and Sons and Workmen	1	10	0
Workmen of Messrs. Perkins and Co.	1	1	0
Mr. Walter Dennison and Workmen	1	1	0
Workmen of Messrs. E. Chadwick and Sons, Dewsbury	0	18	9
Workmen of Mr. J. F. Godham, Greenwich	0	14	6
Workmen of Messrs. Sparrow and Sons, Nottingham	0	9	6

A New Baptist Hall at West Norwood.—Chatsworth Hall, a block of buildings which has just been erected in connection with the Rev. Archibald G. Brown's church at West Norwood, was opened last week. The new hall and its allied rooms, &c, have been rendered necessary by the increase in the Sunday-school work of the church and the need of further accommodation for week-night meetings and other gatherings. The total cost will be about £5,500.

Masters and Men.

Building Trade Wages at Bournemouth.—At a recent public meeting of operatives employed in the building trade the following resolution was carried: "That this meeting is of opinion that the time has arrived when the conditions of labour in the building trade of the district should be governed by working rules, and that taking into account the cost of commodities and rent an increase in wages is necessary; it therefore determines to use its utmost endeavours to achieve these objects."

The Newcastle Building Trade Dispute.—At a meeting of the Northern Counties Federation of Building Trade Employers, held recently, it was unanimously resolved that unless the dispute between the Operative Bricklayers' Society and the Newcastle, Gateshead, and Tyne District Master Builders' Association be settled a general lock-out of the bricklayers in the Northern Counties will take place on November 3rd. Notices to this effect are being sent to the local secretaries of the bricklayers' societies in the Northern Counties.

State of the Building Trades in the Colonies. The October circulars of the Emigrants' Information Office and the annual editions of the penny handbooks show the present prospects of emigration. New handbooks on the West Indies and Malay States have been issued. The season for emigration to Canada is now over, except for persons with capital. In New South Wales, at the Broken Hill mines, there is a good demand for carpenters and masons, engine-drivers, firemen and cleaners, boilermakers, blacksmiths, toolsmiths and fitters. In Victoria there is a good demand, which is likely to continue, for a limited number of thoroughly skilled plumbers on the Melbourne drainage works, and for iron-workers. The Chief Inspector of Factories, in his annual report just issued, states that there was an increase of 3,702 persons employed in factories and work-rooms in 1899 as compared with the numbers in 1898. These figures show a great improvement in trade. In South Australia, Tasmania, and Queensland the supply of labour is mostly equal to the demand. In Western Australia the supply of men at Coolgardie in the building and other trades, of miners, and unskilled labourers is greater than the demand At Perth the building and other trades have improved, but the supply is about equal to the demand. In agricultural parts, as at Albany. Toodyay, Geraldton and Dongarra, the supply of all kinds of labour is equal to or in excess of the demand. It is difficult for clerks, accountants, bookkeepers, and that class of labour to find employment. The last reports show that there was plenty of work in New Zealand. At Auckland and Napier the building trades have been busy. At Wellington the building and engineering trades have been very busy. At Nelson the building and engineering trades have been brisk. At Christchurch the building trades have been particularly busy, bricklayers having been in special demand; men in the engineering trades have also been fully employed. At Dunedin carpenters, bricklayers and stonemasons have been fully employed, but painters and plasterers have been slack. At Invercargill the building trades—in which competent carpenters have been specially wanted—and the engineering trades have been very busy. Persons are warned against going to South Africa in search of work, so long as the war lasts. They will not be allowed to proceed up country. There are large numbers of persons there at the present time who are out of employment.

Cornelly Church has been reopened after restoration. The chancel was restored some years ago, and the remaining parts of the church, including nave, Gregor aisle, tower and porch, have now been restored. The church is probably of the thirteenth century, with an interesting carved font of great antiquity. An entirely new roof has been erected, the walls have received much repair, and there has been fresh glazing. Above £700 has been spent on the work.

Keystones.

A New Electric Light Station at Dartford is to be erected. Messrs. Hesketh and Stokes, of 110 Cheapside, E.C., are the architects.

A New Drill Hall at Henley-on-Thames has been erected for the use of Rifle Volunteers, Yeomanry, and Church Lads' Brigade.

Messrs. Harrington and Ley, architects, of 65 Bishopsgate Street Without, E.C., are erecting a warehouse at Silvertown for the American Radiator Company.

Workmen's Dwellings at Plymouth. — The Local Government Board have given their sanction to a proposed loan of £10,215 for the erection of additional municipal workmen's dwellings at Prince Rock, Plymouth.

A New Church at Bournemouth, dedicated to St. Andrew, has been opened in Malmesbury Park. Another church dedicated to St. Ambrose has been erected on the West Cliff at a cost of £12,500, to accommodate 700 persons.

A New Congregational Chapel at Barry Dock is being built at the corner of Tynewydd Road and Wyndham Street. Mr. George Thomas, F.S.I., architect, Cardiff, is the architect, and Mr. J. Prout, Tynewydd Road, Barry Dock, the builder of the chapel.

A new Church at Glass Houghton, Castleford, is being erected. The first section will seat 300 persons, and will cost £3,500; but when completed the Church will hold 600 persons, and cost £7,000. The architects are Messrs. Demaine and Brierley, of York.

Mr. Edwin Bradbury has gained the prize of £10 10s. offered by the Royal Institute of Architects of Ireland for the best sketch design of a town hall for a provincial town prepared by a member of the Architectural Association of Ireland. The Institute have decided to offer a similar prize next year, but in the form of a travelling studentship.

Mr. L. J. Wood, the well-known painter of Continental towns, died last week at the age of 87 years. He was born in Islington in 1813, and at an early age developed a talent for art. The works of David Roberts, R.A., greatly influenced him. He never received any instruction in art but what he derived from his early friendship with the late J. D. Harding.

Plympton Cross.—The cross discovered about sixty years ago in the walls of the Old Guildhall, Plympton St. Maurice, and removed to the churchyard, has just been restored and placed on the south side of the church. The shaft—a monolith 10ft. in height—is a specimen of fifteenth-century work. It was hewn out of stone that was freely used in the building of the two local churches, the Old Guildhall, and the Old Priory—a kind found on Roborough Down. There is now an octagonal base of three steps, and a new top forms the arms. The total height of the erection is 15ft.

St. Gabriel's College, for the training of female teachers for elementary schools, has been installed in new permanent buildings at Kennington, which were formally opened last week. The permanent building has been erected at a cost of £42,000, towards which about £20,000 has been obtained. It is as yet unfinished. The site, about four acres in extent, overlooks Myatt's Fields. The building will provide accommodation for 80 resident students and the same number of day students. The building consists of chapel, refectory, dormitories and class-rooms.

A New Church at Ealing, S.W., dedicated to St. Augustine, in Lillie Road, was consecrated last week. The church in its present state—the nave and aisles only being completed—will accommodate 500 worshippers. There is still to be built the chancel, side chapel, organ chamber, and vestries. The whole is estimated to cost £7,000. The architects, Messrs. J. E. K. and J. P. Cutts, have adopted the Fifteenth Century Perpendicular style, and the edifice is constructed of Bath stone faced with red brick externally and the walls plastered inside. The nave is six arches long, with an open timber roof and a wood block floor.

A Church on Mount Zion is being erected on the site of the Dormition of the Holy Virgin. The site was given to the Emperor William by the Sultan on the occasion of His Imperial Majesty's visit to Jerusalem.

The Colston Hall, Bristol, which was destroyed by fire on September 1st, 1898, has been rebuilt, and is to be reopened on November 27th. The hall will accommodate between 4,000 and 5,000 persons, and will contain an organ costing £5,000.

A Chapel for the Missions to Seamen in the port of Manchester is to be erected. The chapel, estimated to cost about £1,500, will be part of a block of mission buildings. The whole will cost upwards of £4,000. A site has been obtained at a cost of £900.

At St. John the Baptist's Church, Penzance, new stalls and a pulpit have been dedicated. The new additions are of massive character, and constructed entirely of West Country grown oak. They are in the fifteenth-century style of Gothic. The stalls accommodate sixteen men and eighteen boys. The fronts are pierced, and ornamented by carved and tracery work. The new pulpit is octagonal on plan and has been placed upon the north side of the sacred fane, to the westward of the chancel arch. It is profusely carved and diapered, the spandrels above the ogee arches being filled by shields and mantling. These additions have been carried out by Messrs. Harry Hems and Sons, of Exeter.

A London Improvement.—A letter from Mr. C. H. Brodie shows a curious state of affairs in respect to an important street improvement at the junction of Oxford Street and Shaftesbury Avenue, W. Owing to proposed building operations, there is just now the opportunity of removing an unsightly projection and equalising the alignment of the curve. This architectural embellishment is likely to remain unaccomplished, for the most absurd of all reasons—that each of the authorities concerned says that it is the other's business, although they both agree that the improvement should be carried out. The St. Giles's District Board of Works said the London County Council was the party to act, while the Council, when applied to, pointed to the other. Probably by the time they have decided the question the new buildings will be finished and the symmetry of the street spoiled.

New Infirmary for St. Austell Workhouse.—At a meeting of the St. Austell Guardians, Mr. H. Preston Thomas, Local Government Board Inspector, said, with reference to the proposed additional infirmary accommodation for the workhouse, it was not a very advisable proceeding. He had strongly advised the Local Government Board to erect a new building, three storeys high, and about 30ft. behind the existing one. The cost would be about £3,500, whereas to patch up the old building would probably cost £2,000. It was also suggested by the Local Government Board architect that the centre portion of the existing building be demolished, so that the two wings could be utilised if needed in future years, and connected by corridors. It was resolved to have a new building.

A New Opera House at Weston-super-Mare is to be erected. The principal elevation will front Regent Street, and the building will be in the Italian Renaissance style. Freestone will be mostly used with an admixture of red brick. The interior will be treated in the same style both in construction and decoration. Great care has been taken to safeguard the public against panic or its results. Ample exits from all parts of the building are to be provided, and all the doors will open outwards, and will be fitted with patent panic locks. Seating accommodation will be provided for about 1,200 persons, a good view of the stage being obtained from all parts of the house. There are two tiers, each of good depth, supported by cantilevers. Attached to each tier will be a saloon and foyer. The whole will be lighted by electricity, and ventilated and heated on the most approved principles. The architects are Messrs. R. Milverton Drake and Pizey, of Bristol.

The new Gaiety Theatre is to be commenced in about two months' time.

A Stained-glass Window has been lately erected in Frithelstock Parish Church. The window is composed of three lights and tracery, and is situated under the tower. The restoration of the tower is now complete.

The Central Hall at Bermondsey, S.E., which has recently been erected for the South London Wesleyan Mission, was erected from designs by Messrs. C Bell, Withers, and Meredith, architects, of 3 Salters' Hall Court, E.C., and not by the Rev. H. T. Meakin, as stated on page 180 of our issue for October 3rd.

Workmen's Dwellings at Liverpool.—The Insanitary Property and Artisan's Dwellings Committee have resolved to recommend the City Council to approve a scheme for the erection of dwellings for the labouring classes, in accordance with plans prepared by the deputy surveyor, and to apply to the Local Government Board for their sanction to the borrowing by the Council of £53,500 for the purpose of carrying out the scheme. The dwellings are to be in Kerr Street, Newsham Street, Shelley Street, Clive Street, and Arley Street.

Architects' Benevolent Society.—The fiftieth annual report of the Council states that the desire, frequently expressed, that every architect in active practice should become a contributor, is still very far from realisation. The amount received in subscriptions during the past year was £469 3s., which is a slight decrease on the previous year. The proposal to celebrate the fiftieth anniversary by a festival dinner has been deferred till next year, on account of the many calls on the country made by the war in South Africa. The honorary treasurer of the Society is Mr. W. Hilton Nash, Bush Lane House, Bush Lane, Cannon Street, E.C.

Mr. Walter Hanstock, principal in the firm of W. Hanstock and Son, architects, of Batley and Leeds, died last week. Mr. Hanstock has held a prominent place in his profession for at least two decades, and structures in England, Ireland, Scotland and Wales have been erected to his designs. The new baths at Leeds and Batley were his creations, the abattoir recently built by the Leeds Corporation was from his plans, and the designs accepted a few months ago by the Batley Corporation for a new Town Hall were his also. The deceased leaves a widow and one son, Mr. Arthur Hanstock. Mr. Hanstock, jun., has been in partnership with his father for two or three years.

The New War Office Buildings.—A year's work on the foundations for the New War Office buildings in Whitehall has resulted in the excavation of a huge pit some 30ft. in depth, not yet wholly cleared as regards the central portion, but finished around the boundaries of the site, to allow of the concrete work of the "dry area" to be in the meanwhile proceeded with. Like the new series of buildings for the Admiralty across the way, the New War Office will be built in what will practically be a water-tight pit, especial measures having to be adopted in the raising of heavy buildings on these sites, in view of the still moist and unstable character of the subsoil, little distant from, and at a not much higher level than, the Thames.

Holborn to the Strand: Exhibition of Designs.—The Improvements Committee of the London County Council reports that the plans of buildings to be erected fronting on the Strand and on the crescent road to be formed between Wellington Street and Clement's Inn, will be exhibited for nine days at the Gallery of the Royal Society of Painters in Water Colours, Pall Mall East. The Committee suggests that on October 25th the gallery should be open only to members of the Improvements Committee, and on October 26th and 27th to members of the Council and their friends, from 10 o'clock a.m. until 6 o'clock p.m., and that the public should have admission, without payment, on October 29th to November 3rd inclusive, from 12 o'clock at noon until 8 o'clock p.m. The names of the architects will not be known until after the exhibition has taken place.

New Patents.

These patents are open to opposition until November 19th.

1899.—Bacterial Filter Beds.—18,061. W. D. SCOTT MONCRIEFF, 14 Victoria Street, Westminster, S.W. According to this invention air is drawn downwards through the bed in order to extract carbonic acid gas and other gases as they are formed by the organisms, which gases are removed by fans or other suitable mechanism. Perforated half-channel pipes are laid over the bottom of the bed and communicate with a side conduit, at a suitable point in the crown of which the fan is mounted.

Bricks, Tiles, &c.—18,442. R. STANLEY, Manor Court, Nuneaton. The object of this invention is to give to a brick or tile a facing or coating for the purpose of imparting some particular quality, colour, vitrification, or finish. For instance, a red clay brick of a bad colour may be faced to resemble a better clay. This is accomplished by spraying the inside of the die-box with liquid or dust immediately prior to the entrance of the brick.

Slotting Doors.—20,132. J. FLOOKS, 14 Church Road, Watford, Herts. On the door, in the required position, is fixed a frame carrying an auger mounted on a cross-piece which is connected with a screwed spindle at each side. When the auger is turned the cross-piece advances, carrying the auger with it, and so forming a slot in the door.

Tramway Rails.—22,993. L. COOPER, Central Bank Chambers, Leeds. The rail is made in two parts longitudinally, each carrying half the groove for the wheel. When the groove is worn to such an extent that repair is needed, it is only necessary to remove one half of the rail.

1900.—Partitions.—13,052. E. PRÜSS, 34 Cöthenerstrasse, Berlin. The partition consists of a stiffening framework of hoop iron stretched across the space to be filled and a double wall of thin bricks. The iron strips do not pass through, but over, one another, and the bricks fit on each side, the whole being held together by mortar. Each square of the framework is filled with sixteen bricks, eight on each side.

The following specifications were published on Saturday last, and are open to opposition until November 26th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—18,827, SINNBERG atmospheric gas burners. 18,879, WEBB, interlocking tiles. 19,421 JONES, PIERCE & TREGLOWN, rock drills. 19,553, CHISHOLM, swivel joints for bay window curtain-poles. 19,921, BASSETT, plastering of walls, ceilings, &c. 19,955, ADAMS, hot and cold water taps. 20,432, GRUNDY, GRUNDY & GRUNDY, automatic valves for water and other fluids. 20,690A, WILKINSON, gas burners. 21,173, PICKLES & PICKLES, application of balanced cranks to wood-cutting and sawing machines. 21,801, WINTERFLOOD, water-heaters and automatic valve attachments for them. 22,141, TOYE, lifts. 22,167, BUSCH (*Busch*), lifting jacks. 22,247, PRESTON, ships' closets. 22,518, DALE & DALE, tool-grinding machines. 22,893, PERRIN, cutter heads for wood-working machinery. 22,997, ROBINSON, wrenches. 23,229, WINKLER, incandescent gas lamps. 23,348, FIEGEHEN, grabs and excavators. 24,408, STALEY & PARKER, sanitary pipe machines. 24,511, WINTERFLOOD, water-heating apparatus. 24,659, GRAHAM, hot coke conveyors. 24,674, SMITH, window and wall cleaning appliance. 24,883, HADDAN (*Friedinger*), wooden wall plugs.

1900. 4,305, BROWN AND BECK, devices for closing, checking, and regulating swing and other doors. 6,739, SCHUCH AND WOLF, sash balances for windows. 7,933, PINK AND VULKAN GESELLSCHAFT FÜR SELBSTZÜNDENDE GLÜHKÖRPER MIT BESCHRÄNKTER HAFTUNG, incandescent mantles. 7,967, LLEWELLYN, picks for mining and other purposes. 8,005, LEVY, apparatus for disinfecting by steam under pressure. 9,512, IVES, treatment of sewage. 11,995, SONSALLA, ventilating doors. 12,240, SMITH, acetylene gas generators. 12,424, HARTUNG, means for forming prismatic sheet glass. 12,849, MORTON, pumps. 12,916, SHEPPARD, device for casting wire glass. 12,917, SHEPPARD, device for casting sheet glass. 13,545, HUDLER, incandescent gas burners. 14,160, SMITH, acetylene gas generator.

New Companies.

New Sunlight Incandescent Co. (1900), Ltd.

This company was registered on October 3rd with a capital of £100 in £1 shares to acquire the goodwill, business, trade marks, and designs of the New Sunlight Incandescent Company, Limited (incorporated in 1899). The directors are the directors for the time being of the Welsbach Company.

Herbert W. Periam, Limited.

This company was registered on October 3rd with a capital of £15,000 in £1 shares to acquire and carry on the business of bolt, nut, screw, rivet, washer, and roofing nail manufacturers, &c., now carried on by H. W. Periam at 25, 26, and 27 Floodgate Street, Birmingham, and the business of factors of and dealers in similar goods now carried on by the said H. W. Periam and J. Pearce, trading as John Pearce, at 242 Mosley Street, Birmingham. The first directors (to number not less than three nor more than seven) are H. W. Periam, H. B. Periam, and C. J. Pearce. H. W. Periam may retain office so long as he holds 2,000 shares.

New Expanded Metal Company, Limited.

This company was registered on October 3rd with a capital of £35,000 in £1 shares (8,000 deferred) to acquire the business of working certain patents relating to metal trellis or lattice work now carried on by the Expanded Metal Company, Limited (in liquidation), and to carry on the business of metal workers, &c. The first directors (to number not less than three nor more than twelve) are W. B. Close, J. Cranmer, A. de Wette, C. Lambert, and W. H. P. Stevens, with power to add J. F. Golding to their number as managing director. Registered office: 39 Upper Thames Street, E.C.

CONTRACTS OPEN.

TO BUILDERS AND CONTRACTORS.

The Committee of the Walsall and District Hospital desire to receive TENDERS for the ERECTION of NURSES' HOME and OUT-PATIENTS' DEPARTMENT in the Wednesbury Road, according to Plans and Specification prepared by Messrs. Bailey and McConnal, Architects, Bridge Street, Walsall, at whose offices the plans, &c., may be seen and Bills of Quantities obtained on payment of One Guinea, which will be returned on receipt of a bonâ-fide Tender.

Tenders, sealed and endorsed, are to be delivered at the Architects' Offices not later than TWELVE o'clock midday TUESDAY, October 30th, 1900.

The Committee do not pledge themselves to accept the lowest or any Tender, nor will they consider any Tender from a Contractor who will not bind himself to pay the standard rate of wages in the district.

S. WELSH, Secretary.

October 1900.

TO BUILDERS and CONTRACTORS.

The Waltham Holy Cross School Board are prepared to receive TENDERS for ALTERATIONS and ADDITIONS to the OUT-OFFICES at the Board Schools in Milton Street, Waltham Abbey, in accordance with plans and specification, which may be inspected at the Office of the Clerk to the Board at Waltham Abbey during office hours.

Tenders, marked "Tender for Alterations to School Buildings," must be delivered at the Clerk's Office not later than TWELVE noon on MONDAY, OCTOBER 29th inst.

The Board do not bind themselves to accept the lowest or any Tender, and the acceptance of a Tender will be subject to approval by the Board of Education.

By order of the Board,
H. GOUGH,
Clerk.

Waltham Abbey,
October 1900.

GLAMORGAN QUARTER SESSIONS AND COUNTY COUNCIL.

ALTERATIONS AND ADDITIONS TO MERTHYR POLICE STATION.

The Standing Joint Committee of the Glamorgan Quarter Sessions and County Council is desirous of CONTRACTING for ALTERATIONS and ADDITIONS to Merthyr Police Station

Contractors will be required to pay their workmen the recognised rate of wages.

Plans and Specification of the Works required may be seen, and copies of the Bill of Quantities obtained, by those desirous of tendering, at the Merthyr Police Station and at these Offices.

Sealed Tenders are to be delivered to me, together with the names of two substantial sureties, not later than WEDNESDAY, the 24th inst., marked outside "Tender for Alterations and Additions to Merthyr Police Station."

The Committee will not necessarily accept the lowest or any Tender.

T. MANSEL FRANKLEN,
Clerk of the Glamorgan County Council.

Glamorgan County Council Offices,
Westgate Street, Cardiff,
October 1900.

TO BUILDERS.

The Commissioners of H.M. Works and Public Buildings are prepared to receive TENDERS for the ERECTION of a NEW COUNTY COURT at MIDDLESBROUGH.

Drawings, Specification, and a Copy of the Conditions and Form of Contract may be seen on application at the Offices of the Registrar, County Court, Middlesbrough.

Bills of Quantities have been prepared for the use of Builders by Messrs. H. Gritten and Son, of 8 Princes Street, London, S.W., and together with Forms of Tender may be obtained at H.M. Office of Works, Storey's Gate, London, S.W., on payment of One Guinea. The sums so paid will be returned to those persons who send in Tenders in conformity with the conditions specified below.

The Commissioners do not hold themselves responsible for the accuracy of the quantities, nor do they bind themselves to accept the Lowest or any Tender.

Tenders are to be delivered before 12 o'clock noon on MONDAY, the 22nd instant, addressed to the Secretary, H.M. Office of Works, &c., Storey's Gate, London, S.W., and endorsed "Tender for New County Court, Middlesbrough."

H.M. Office of Works, &c.,

SAFFRON WALDEN.

MR. CHEFFINS will SELL by AUCTION, on FRIDAY, OCTOBER 19th, 1900, by direction of Messrs. D. Dix & Sons, who are relinquishing the building branch of their business. the whole of the BUILDER'S PLANT and STOCK-IN-TRADE, embracing 12 h.-p. horizontal engine, saw bench and circular saws, Reynolds' planing and thicknessing, mortising and moulding machines, steam band-saw machine, countershaft, boring machine, iron appliances for concrete building, hydraulic cement press, ironmongery and earthenware, including rain-water fittings, guttering, piping, stoves, gas apparatus for greenhouse heating, wrought iron fence and gate, drain pipes, bends, half-bends, junctions, &c, sanitary fittings, oak, pitch-pine, and deal planks and boards, compo. boards, roofing and paving tiles, benches with patent vices, wooden shed 22ft. by 9ft., builder's van and 3 spring carts, comfortable phaeton, pony gig, strong black cob, useful brown pony, 4 sets of brass-mounted harness, large quantity of firewood and numerous other effects (about 400 lots), upon the PREMISES in West Road. Sale to commence at HALF-PAST TEN o'clock precisely.—Catalogues may be obtained of Mr. CHEFFINS, Saffron Walden.

TWICKENHAM.—Highly valuable FREEHOLD PROPERTY, comprising two important riverside residences, with extensive grounds. With possession.

MESSRS. VENTOM, BULL & COOPER will sell by AUCTION, at the MART, Tokenhouse Yard, E.C., on WEDNESDAY, NOVEMBER 7th, at TWO o'clock precisely, in lots, the important and very valuable FREEHOLD PROPERTY, comprising the delightful historic residence known as Radnor House, Crossdeep, Twickenham, together with beautifully laid-out grounds, meadow land, modern stabling, green and forcing houses, farmery, &c. Also adjoining Radnor House, the valuable residence, known as Crossdeep House, with stabling, outbuildings, and well-timbered grounds, and four freehold cottages in Chillingworth Gardens, the two properties having a river frontage of about 520 feet, the whole covering an area of about 15 acres. The property has important frontages to four roads, and possesses exceptional value for building purposes, for which it is immediately ripe and could be developed without affecting the enjoyment of the residences.—May be viewed by orders, to be obtained only of the Auctioneers, and particulars and conditions of sale may be had of Messrs. WRIGHT, BECKET & WRIGHT, Solicitors, 17 Water Street, Liverpool; at the Mart; and of the Auctioneers, 35 Old Jewry, E.C.

FREEHOLD BUILDING LAND, comprising about 8 acres, within a few minutes' walk of Willesden Junction.

MESSRS. E. & H. LUMLEY will SELL by AUCTION at the MART, Tokenhouse Yard, E.C., on TUESDAY, NOVEMBER 13th, 1900, at TWO o'clock, in one lot, unless previously sold, the valuable FREEHOLD BUILDING LAND, tithe free and land tax redeemed, comprising about 8 acres, situate in the main road (Harlesden Lane, opposite Sellons Avenue and Springwell Avenue), near High Street, Harlesden, and Willesden Junction, and ripe for development into shop and villa plots or for the creation of ground rents. Plans, particulars, and conditions of sale can be obtained at the Mart, E.C.; of the Solicitors, Messrs. THOROLD, BRODIE & BONHAM-CARTER, 4 Regent Street, S.W.; and of the Auctioneers, Messrs. E. & H. LUMLEY, St. James's House, 22 St. James's Street, S.W.

GENERAL or WORKING FOREMAN (young man). Sober and energetic. Good manager of men, good draughtsman. First-class Advanced Certificate Building Construction, Assoc.San Inst. Can survey and level and measure up. Carpenter and joiner. Good testimonials.—R. S., 618 Holloway Road, N.

PLUMBING, Gas, Hot-water, and Sanitary WORK WANTED. At price or otherwise all tools. Labour, or labour and solder. Town and country.—Address, C. F. B., 13 Hertford Road, Lower Edmonton, N.

TO BUILDERS.—Painting and Decorating Work Wanted by reliable Man, either to find labour only, or find everything, as may be arranged.—Box 1,504, Office of the BUILDERS' JOURNAL.

APPOINTMENTS VACANT.

CLERK WANTED for DAY BOOK; must have had similar experience in Brick Works or Builders' Merchant's Office; state age, experience and salary required.—STANLEY BROS., LIMITED, Nuneaton.

MASONS WANTED for Banker and Fixing.—Apply, W. TINDALL, Builder, Cambridge.

TELEGRAMS: "Dividitore, London." **LONDON** TELEPHONE: No. 1011 Holborn.

DRAWING & TRACING OFFICE.

98 Gray's Inn Road, Holborn, W.C.

(Adjoining Holborn Town Hall.)

MANAGER, JOHN B. THORP, ARCHITECT & SURVEYOR.

Cheques Crossed: The London, City, and Midland Bank, Ltd.

Office hours—Nine to Six. Saturdays One.

Established 1883.

For the PROMPT and EFFICIENT execution of all work usually required by the PROFESSION, such as

WORKING DRAWINGS, TRACINGS, PERSPECTIVES, SURVEYS, COMPETITION DRAWINGS, PHOTO-COPIES (or SUN PRINTS), Quantities, Specifications LITHOGRAPHED. MODELS, TYPEWRITING, &c.

TRACING and PRINTING Rooms, HATTON GARDEN, connected by Private Telephone.

LONDON PLATE-GLASS INSURANCE CO., LTD.

Head Office: 49 Queen Victoria Street, E.C.

Ten per cent. of the Premiums returned every six years in cases where no claim has arisen.

APPLICATIONS FOR AGENCIES INVITED.

LIBERAL TERMS FOR BUSINESS INTRODUCED.

"BUILDERS' JOURNAL" INSURANCE POLICY.

FREE INSURANCE. £100

Will be paid to the legal representative of any man or woman (railway servants on duty excepted) who shall happen to meet with his or her death by an accident to the railway train in which he or she was travelling in any part of the United Kingdom on the following conditions :—

1. That at the time of the accident the passenger in question had this paper in his or her possession.
2. That prior to the accident the passenger in question had affixed his or her usual signature in the space provided below.
3. That notice of the accident be given to the Corporation guaranteeing this insurance within seven days of its occurrence.
4. That death result within one month from the date of the accident.
5. That no person can claim in respect of more than one of these coupons.
6. The insurance will hold good from 6 a.m. of the morning of publication to 6 a.m. on the day of the following publication.

THE BUILDERS' JOURNAL & ARCHITECTURAL RECORD

October 24, 1900. No. CCXCVIII.

Effingham House, Arundel Street, Strand, W.C.

An Architectural Causerie.

Sham Architecture. In the October number of the "Strand Magazine" there are two articles dealing with architecture, one interesting and readable, the other distinctly bad. In the former, entitled "Which is the Finest Building in the World?" the selections of leading architects are given—Professor Aitchison chooses the Pantheon at Rome; Mr. Alfred Waterhouse, St. Mark's, Venice; Mr. Phené Spiers, Sta. Sophia, Constantinople; Mr. John Belcher, Greenwich Hospital; Mr. Norman Shaw, St. George's Hall, Liverpool; Mr. William Emerson, the Tâj Mahâl, Agra, India; Mr. T. E. Collcutt, St. Paul's Cathedral; Mr. Thomas Blashill, Chartres Cathedral; and Mr. Walter Emden, Michael Angelo's Chapel, Florence. It is desired now, however, to draw attention to the article on "Artificial Rock Formation," in which the author displays the grossest incompetence to deal with architectural construction. The article bristles with absurdities, manifestly the results of a knowledge which is at once limited and peculiar.

The suggestion to form "quaintly-fashioned" artificial rocks on stretches of flat coast-line is bad enough, but it is not the quarrel with this really pernicious article. A magazine such as the "Strand," with its immense circulation, has in its power great opportunities for good or evil. What then can be said of an author who openly and unblushingly advocates and defends the erection of artificial ruins as adjuncts to natural scenery? "While allowing that such work is undoubtedly of a deceptive nature, it cannot be denied that the fraud is entirely harmless in character." Mr. Best has not even mastered the first principle of the building art, and it would be an act of charity to inform him that in architecture, shams are the greatest of all sins. If a building is a sham, then its existence is useless—it has no mission, and is certainly not a fit subject for eulogy in the pages of a popular magazine.

Later on, one is told that the artificial ruin "is certainly a thing of beauty, fascinating in conception, and a picturesque adjunct to the best work of the artist in scenery." An artificial ruin is not "a thing of beauty" since it has no use, neither is it "fascinating in conception," as, beyond a very weak desire to copy, it has no motive; and lastly it cannot be an "adjunct to the best work of the artist in scenery"; it is a sham, and in nature nothing is unreal or useless. "At the same time, a ruined tower or gateway forms one of the best means of concealing unsightly objects from view, and is capable of serving a variety of useful purposes." An author who deliberately says that the motive of architecture is to hide artificial eyesores is obviously not a fit and proper person to hold forth on the canons of any art, much less on those of the most exacting of all. A view of one of these sham abominations—a "home-made abbey"—is given on page 399, and as the original is "composed chiefly of brick," one thanks heaven that, so far, the secret of colour-photography is unsolved. This sham ruin is not even a passable copy of a genuine abbey, and its utterly false proportions are quite in accord with the unholy motives which suggested its erection. Again, on page 400, we are shown

a reproduction of a spurious Norman castle (the learned author of the paper charitably withholds the name of the builder) in Hertfordshire. "It is built entirely of flint, dressed with artificial stone. Many an astute antiquarian (*sic*) has been deceived by the Hertfordshire 'ruin,' and it is by no means improbable that in the course of a century or two the secret of its construction will die out, and this 'Norman castle' . . . may then be regarded as one of the most finely preserved specimens of early architecture in the kingdom." Let Mr. Best make no mistake. Immediately the Hertfordshire people develop the slightest regard for ancient works, or discover the remotest germs of architectural taste, this wretched sham will be utterly destroyed and made into a funeral cairn for its unhappy author as a warning to others; then perhaps we shall be spared another exhibition of an unhealthy admiration for things which should be offensive to those who presume to write for the edification of the lay public. J. R. L.

Those Little Things that Mean so Much. Just as in the conduct of life, in the making of a career, there are the little graces that mean so much in gaining success—whose absence is so greatly noticed, to the final confusion of him who has them not—so there are the minor details in the proper ordering of a building or a town which make or mar its appearance. This, which seems by way of being an apothegm, is unhappily forced upon one's notice by a plentiful lack of the graces and an assertive intrusion of the petty ugliness of life in places where they have no sort of right to exist at all. There is a fatal facility in the production of the positively ugly and a wicked wrong-headedness in the perpetration of the commonplace just where it mars the beautiful or the sublime (and so by contrast becomes more hideous than uglier things in less soulful surroundings) which *might* make angels weep and *does* make mere mortals angry or despondent, accordingly as their natures are choleric or melancholic. That these little solecisms mean little or nothing at all to the mass is a good thing for the mass, always supposing that such hindrances to the enjoyment

of beauty could exist concurrently with the million educated up to keener artistic perceptions. With the supposition that they could, it is well for the mass that it eats and drinks and takes things as it finds them and sees nothing wrong, although the best view of some hallowed spot is desecrated by a gasometer, and though the babbling rills and lazy rivers of a once unpolluted countryside are turned to the hue of ink or glisten with the filthy iridescent hues that derive from the waste of some modern factory. Nor are the crowds alone reckless of these things. The new-rich, having passed their lives in the getting of riches, pay the penalty of having a true sense of the beautiful denied them, just as, inversely, the artist's penalty for his life-long pursuits is an exaggerated perception of the sordid where it exists in uncongenial surroundings. One sometimes queries the advantage of a training which reveals these blemishes in such morbid prominence and renders it almost physically painful to see, as one may often see in our cathedrals, the naked stove-pipes of the heating apparatus reared up against Norman arch or Early English tracery, their leaky joints blackening with coal smoke the revered architecture that has hitherto survived, unstained, the breath of close upon 900 years. Such things lead to the impious thought that, after all, Deans and Chapters may not necessarily be the most enlightened custodians of these historic piles! It is impossible to find the fitness of things exemplified in cathedral naves or transepts by the unblushing presence of a home-made coal-scuttle for the feeding of the stoves, made from Tate's cube-sugar cases; yet such things may be observed. We are not advocating such *tours de force* as those resorted to by the would-be artistic housewives of a decade ago, who painted their coal-scuttles with marguerites and sunflowers, and fondly imagined that the fact of their containing coals was cloaked thereby; but there is surely somewhere to be found a middle course between brutal frankness and insincerity.

It would be easily possible to multiply instances of the little vulgarisms that bring the soaring fancy down to earth again: the hoardings that display commonplace advertisements athwart the meadows as you speed by in the train, and while your spirit communes with the gods, suddenly succeed in distracting your attention with the insistent admonition at the tail end of some monstrous puff:—"but see that they *are* So and So's." The wily advertiser is justified of his guile, although you curse him for his bad taste; for the mind instinctively tries back to recover the beginning of the announcement, and when the advertisement recurs (as of course it is bound to do), greedy curiosity takes in the information; and the pills or soap, or what not, is duly impressed upon your memory. But what avails it to multiply instances? Everyone can do it for himself, so fruitful are the times!

C. G. H.

Red Lion Inn, Glastonbury.

IN an old town like Glastonbury there is generally much to interest the architect and artist, little details he can sketch, suggestions for design which he can make use of at a later date. The drawing by Mr. W. Lee Clarke of the old Red Lion Inn at Glastonbury is an example of this, with its quaint roofs and archway. The inn is situated in the Market Place, and the passage shown leads to the Abbot's Garden, which is situated at a higher level at the back of the house.

On Reflection.

Manchester Infirmary.

WHILE the Council in London is concerned about one Piccadilly, the Manchester authorities are concerned indirectly about another: this, however, not in connection with a street-widening scheme, but as part of the proposal for the new Royal Infirmary, which is to be built on the present site. Until quite recently the Medical Board of the Infirmary was most hostile to any system other than that of pavilions, but there has been a change of opinion sufficient to cause the Board to admit that an efficient hospital might be built on a non-pavilion principle. The difficulty in the selection of plan is chiefly due to the fact that the available space is limited, and pavilions require more ground than buildings erected on any of the other systems. According to the last plans drawn up for Manchester, the space actually occupied by the buildings would have been only five per cent. more than that occupied at present; but on account of the spreading of the pavilions all the Piccadilly frontage would have been taken up, making it more like a street than an open space. These plans were therefore rejected, and no decision has since been arrived at with regard to the type of plan to be adopted. The late Sir Douglas Galton stipulated that the three essentials in hospital design were light, air, and warmth. Since his day there have been great improvements in ventilation and sanitation, but even now there is much difference of opinion on the former subject. As regards light, the pavilion system undoubtedly offers the best solution; but it is found that with a range of windows on each side there is a considerable cooling surface of glass, and consequently heating becomes a very difficult matter. The corridor plan (on which the present Royal Infirmary at Manchester is built) has much wider blocks, so that there may be rooms on each side of a central corridor; while the block plan is practically the corridor plan without the corridor, its place being taken by a partition. Each plan has its advantages, though the pavilion principle is the one most generally adopted now. But the Manchester authorities find that it will not suit them, and so they are taking thought before they spend their £200,000.

Hist! The Voice of the F.R.I.B.A.

A JUNIOR in an architect's office will tell you that an F.R.I.B.A. is a being who walks with the gods. But when the junior grows up and learns a little of the true principles of his art—if he does—the image will be blackened somewhat, and there will be patches in what was formerly considered to be a faultless creation. So the F.R.I.B.A. is mortal after all; so mortal that we find one of the race advocating in a contemporary the duplication of Greek terra-cotta vases for the beautification of the garden. Our contemporary is devoted to clay, and the writer goes on smoothly through the well-worn courses of the landscape architect, the harmonising of the building with its surroundings, the use of native possibilities of the site, &c. A specific example is next cited. "The architect has designed a Classic building, and has finished laying out the terraces and other accessories accordingly. Then the owner, having precious little artistic taste as a rule, has a number of miscellaneous terra-cottas on pedestals put up at various points in the grounds. . . . Instead of selecting figures of Classic origin to harmonise with his building . . he usually gets something belonging to the Italian Renaissance, with a few amphoræ and vases of a floral pattern thrown in." Our contemporary has nothing to say against these latter in themselves, but objects that they are out of place in the garden of a Classic building; therefore we are to copy the beautiful terra-cottas of Greece—Niké, Eros, Aphrodite, and the rest. "If it is right for the architect to poach on ancient preserves, so it is for the terra-cotta maker. . . . The Greek archaic period also presents us with many beautiful terra-cotta statues, particularly of the real life of the period—representations of ladies in outdoor costume, gala dress, &c. Athletes, competitors in outdoor games, both Greek and Roman, are the very subjects for the class of terra-cottas of which we are speaking." What will the purists say to this? Reformers have tried to drum nonsense into our heads: of course, two blacks do make a white; it is right for the vase designer to become a copyist out and out, so let us sit down and do likewise. This is fine advocacy. Here lies the way of a national style, and Messrs. Norman Shaw, Halsey Ricardo, Ernest Newton, W. R. Lethaby, E. S. Prior, H. Wilson, Beresford Pite, and a host of others who are attempting—and succeeding—to produce buildings which we can justly claim as our own—they are all wrong, all misguided. So struggle on ye copyists, machine out your duplicates, be careful to have everything exact; then survey your handiwork and thank God that he has given you such talent and that you have put it to such noble use.

A new Indictment.

THE sky-scraper is a production which has been the cause of more outbursts of admiration and disgust than perhaps any other form of building; and so many indictments have already been levelled at it that one or two more now will have less effect, if possible, than those which have preceded them. It is averred that these "climbers" of the bricks and mortar family—or, to be more correct, of the column and girder family—disturb land values in a shocking manner, steal the light and the air, congest the traffic in their neighbourhood, complicate the already very difficult problem of fireproof construction, overtax the sewers and drains that serve them, even produce an alarming mortality among lift men—but why continue? This is not news, with the exception of the item apropos the lift men. But there is a new allegation made by Professor Hyatt, of St. Louis, a weather observer, and no doubt a sane and holy man, which is worth stating. He says that high buildings in a city perceptibly increase the average outdoor temperature. And the good gentleman is right, for, as everyone knows, when the sun strikes on stone wall or slate roof there is a considerable conservation of its energy which is radiated upon suffering humanity around and below. Anyone who has passed a summer in the United States knows what a painful experience it is, the sweltering heat and the oppressive humidity; so that an increase in temperature beyond a certain limit is a thing to be fought like plague. There is yet much to do in the prevention of heat radiation, as there is in heat conservation. It is a common observance that corrugated iron buildings are hot in summer and cold in winter, and the law which they exemplify is the same in regard to buildings of stone and brick. As already stated, there is room for reform in the matter of interior linings for combating natural atmospheric conditions, and enabling the house occupant to enjoy a more equable temperature.

SOUTH-EAST VIEW OF ST. MARY'S CHURCH, BIRKIN, YORKS., SHOWING OLD GATE PILLARS TO HALL.

BIRKIN CHURCH, YORKSHIRE.

By R. A. EASDALE, A.R.I.B.A.

HALF-WAY between Pontefract and Selby, at the side of a quiet country road, stands the little church of the parish of Birkin. With its plain north side and west end facing the road, it attracts very little attention from passers-by who do not take the trouble to make a closer inspection; and as the church is three miles and a half (as the crow flies) from the nearest railway station, and the Great North Road runs past the outskirts of the parish three miles away to the west, it is not surprising that such an interesting and unique piece of architecture is so seldom visited.

The remoteness of the village accounts in some measure for the fact that the archæological value of the church is so little known, and yet at one time the village was the place of residence of men of note. Not one stone remains of the old hall or mansion—the only evidences of such a building are the two quaint stone pillars standing in a field adjoining the church (see illustration). Records at the beautiful seventeenth century rectory tell of the genealogical descent of the family occupying the hall. One Asolf or Oswolf took the name of De Birkin in the twelfth century, and Isabella De Birkin married one D'Everingham.

One of this family restored the church and added the fourteenth century D'Everingham south aisle. Ellen D'Everingham married Gervase, son of Hugh Cressy, Esq., Justice o the Queen's Bench of Ireland, who had issue Everingham Cressy, who died 1644. Dorothy Cressy, only child of Everingham Cressy, married in 1690 Duncan Primrose, of Culross, co. Perth, an ancestor of the present Lord Rosebery.

Another interesting fact showing the importance of this family is that one of the Johns de Birkin was Sheriff of Yorkshire, and carried into effect the order of Henry the Third for the election of an Abbot of Selby named Richard.

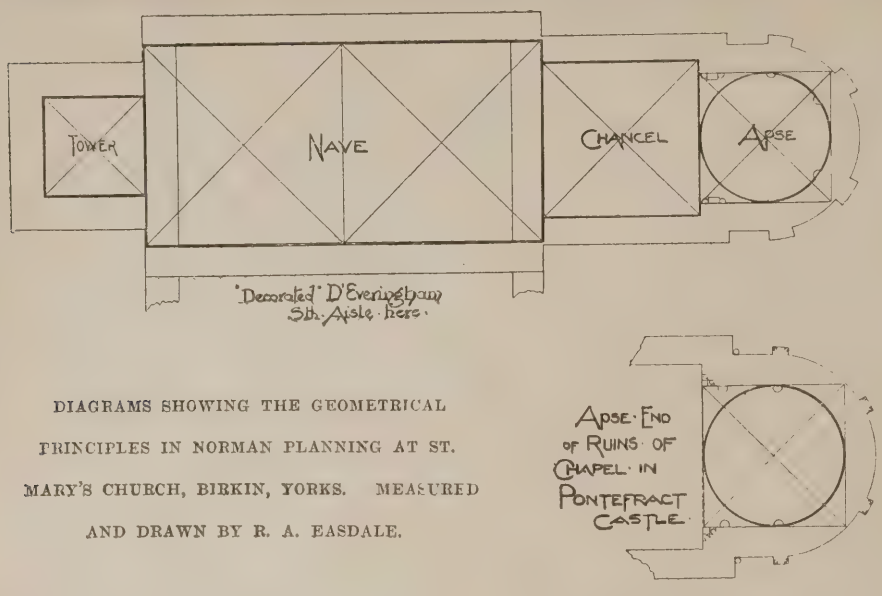
The rectory—a very large picturesque building—stands amongst fine trees in the midst of a beautiful garden. This garden was laid out, about 1722, by the poet Mason, who was also a landscape gardener of repute. Mason was one of a number of literary men who visited a former rector of the parish, amongst whom may also be mentioned Gray, of Elegy fame. (Can it be that Birkin is the real Stoke Pogis?) Two other facts to prove the antiquity of the village may be mentioned—namely, a record that "one Osbert, a priest, of Birkin, sold land to John De Lacy," and, somewhat recently, the unearthing of a Roman or British stone coffin about half a mile from the church. With this preface we may now go on with the description of the building which is the subject of this article.

The novelty of the plan and the beauty of the mouldings and carving appear in no work on English church architecture; indeed, the church is so little known, even in Yorkshire, that when the Yorkshire Archæological Society visited it some time ago many of the members expressed their surprise that such a building existed in their midst. The probable date of the Norman work is 1140. The first plan would be an aisleless nave with square western tower, square chancel, terminating eastward in a semicircular apse. The walls of nave, tower, and chancel are unbuttressed, but the apse has flat pilaster buttresses stopping under a corbelled eaves. The circular apse is somewhat of a novelty in Norman work, most examples having square east ends.

The technical setting-out of the plan, as found out after plotting to a large scale, is very interesting. The chancel is an exact square of 16ft. 6in. internally. The apse is set out by striking a circle of 13ft. 8in. tangential to the inner face of the chancel square (internal faces of nave walls nearly correspond with the external faces of the chancel walls). The nave is a double square to the inner faces of north and south walls, and outer faces of east and west walls, and the tower is a square of half the nave square.

Singularly enough, the ruins of the chapel in the grounds of Pontefract Castle show a similar semicircular apsidal termination as that at Birkin, and after measurement it was found that the same geometrical proportions and method of setting-out had been followed in each case, though the apse in the Castle is somewhat larger than that at Birkin. A reference to the comparative diagram of the two apses on the next page will show that the curve of the apse if continued on its inner face would be tangential to the line of the inner face of the chancel. Whether this interesting fact proves that Birkin church was built through the instrumentality of the De Lacys of Pontefract or not, it certainly points to that theory being more correct than that the monks of Selby did the work, though Birkin is more easy of access from Selby than from Pontefract.

The architectural features of the Norman part of the church are in every way worthy of the grand builders of Norman times.



All the ornamental work is in slight relief; a fact no doubt to which we owe its wonderful state of preservation. The arches are semicircular throughout, and the capitals show a number of varieties of scalloped forms (there are no cushions proper), many combined with angle volutes. The priest's door in the south wall of the chancel has a lintel with a semicircular relieving arch, the tympanum being of solid square stones set anglewise; a probable survival of the *opus reticulatum* of the Romans.

The apse is perhaps the most interesting part of the building, and is one of the earliest specimens of an apsidal ribbed vault in a small church. It is divided into five bays, as will be seen by examining the general plan and detail plan (see centre plates). A transverse rib crosses the apse, the west side of the rib being placed over the tangential point of the curve of the apse with the square of the chancel.

This fixes the position of the vaulting shafts at the springing of the apse, giving a width of 5ft. 4in. between the centres of the shafts. This width of 5ft. 4in. is repeated for the side bays of the apse, leaving a much wider centre bay of 7ft. 5in., the centre window being wider than the side windows. From the shafts on the apse curve two moulded ribs spring, meeting in the semicircular transverse rib across the apse springing. The vault cells between the ribs have a domical curve generated by the semicircular label of the windows, which serves as a sort of wall rib, and the ribs themselves are constructed on the advanced method of actual groin ribs, and not the earlier method of merely radiating ribs on the surface of the semi-domes.

The ribs are in narrow stones throughout (like all the rest of the Norman part of the church), and the keystone in the centre of the

DIAGRAMS SHOWING THE GEOMETRICAL PRINCIPLES IN NORMAN PLANNING AT ST. MARY'S CHURCH, BIRKIN, YORKS. MEASURED AND DRAWN BY R. A. EASDALE.

transverse rib with the intersection of the two radial ribs is in one large stone.

The absolutely logical method of the Normans in their whole procedure is very evident here, especially the way in which the supports of arch and vault are designed to suit arch orders and ribs—a shaft to each order and to each rib.

Notwithstanding the fourteenth century addition of the south aisle, the original "æsthetic" idea of the planning can be readily realised on looking eastward from the dark tower. It is quite evident that the dominant idea was to keep the tower dark (only one window 7in. wide), and the nave dimly lighted, the chancel having a north and south window, and the apse three windows, thus giving a flood of light directly on to the altar. The effect is very striking and charming even now; and this must have been very much more pronounced before the light south aisle was added.

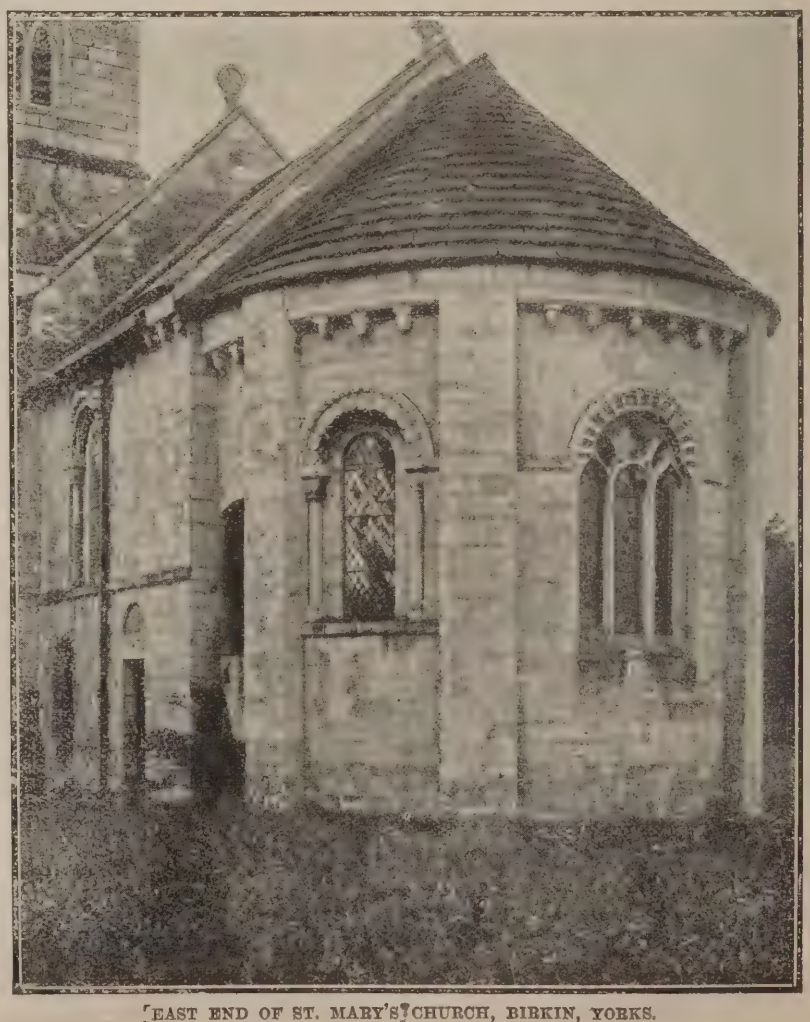
This aisle was erected about the middle of the fourteenth century by the then lord of the manor, D'Everingham. The aisle extends the full length of the nave, and is lighted by a three-light western window and a five-light eastern one, as well as two three-light south windows, all these windows having tracery of different design. Two wide and lofty double-chamfered arches with hexagonal pillar between separate the aisle from the nave. A piscina is placed in the south wall near the eastern wall. (A piscina of evident Norman date was found some time ago in the rectory garden, probably taken from its place in the apse.) Two quaint corbels support the roof timbers of the aisle, one representing a huntsman with dog, bow and arrows.

The addition of the south aisle necessitated the removal of the magnificent Norman doorway from its position in the south wall of the nave to a similar position in the new aisle wall, and the squint in the chancel-arch piers would be pierced at that time. The doorway has three columns and four arches. The outer arch has twenty-four richly-carved plates with zig-zag work on the soffit; the second arch has zig-zag work on face and soffit of different designs; the third arch has the characteristic "bird's-beak" ornament over deep moulds; and the fourth or inner arch is almost without any mould—a very effective arrangement which accentuates the richness of the outer arches.

The capitals of the columns are very elaborately carved, as well as each abacus, the neck mould also sharing in the profusion of ornament. A very notable characteristic of the whole of the Norman ornament is its diversity of detail; no two caps are alike, and ornament is rarely repeated in any position. The corbels round the eaves of the chancel and apse are plain hollows with a head projecting; but those on the north side are of different designs, many being the well-known varieties of axed-work. The lower part of the tower is Norman, as shown by the small size of the stones, and the narrow semicircular-headed windows, with a deeply-splayed opening inside. The upper part of the tower is fourteenth or fifteenth century work, with its characteristic large stones, pointed belfry window, and crocketed pinnacles. The church contains a good example of a Jacobean pulpit (with a sounding board of elaborate design), a stone font dated 1625, several monuments, and one life-size recumbent effigy—with legs crossed—on a tomb.

The whole building was restored in 1883 by Mr. J. Oldrid Scott. This small church is well worthy of study from its unique plan, splendid carving and masonry, and the common-sense of its whole construction. Every part tells of forethought, care, and ability: no bungling or hesitation in building the apse—a most difficult problem in those days, no doubt: and after duly examining the place, and becoming imbued with the true spirit and meaning of it all, one cannot fail to have a feeling of intense admiration for those noble, honest old builders whose very names are forgotten, but whose handiwork remains to this day a thing of wonder and beauty.

ACLAND AND RUSKIN.



THE OXFORD MUSEUM.

THE many-sided life of the late Sir Henry Acland, who died on October 16th at the age of eighty-five, has special significance for us on account of its close connection with the life of John Ruskin and its devotion to sanitary reform. In 1854 Dr. Acland went very carefully into the subject of the sanitation of Oxford, and he showed that the whole place was full of the filthiest cesspools, contaminated wells, badly constructed drains and sewers, and that the narrow streams about the town were horribly befouled by its drains. The light thrown upon the state of things here led to a great sanitary reform, and the stir up at Oxford afforded a lesson for the whole country. In a work of this kind Dr. Acland was in his element. He was serving God and man, and he gloried in such work. He wrote and spoke much on insanitary villages. In 1866 he was appointed a member of Mr. Gathorne Hardy's Cubic Space Commission, and he was a Royal Sanitary Commissioner from 1869 to 1872.

Ruskin on many of his visits to Oxford as professor was Acland's guest, and Acland seldom if ever missed being present at Ruskin's lectures. Other and more enduring witness of their friendship exists. In 1853 Acland was with Ruskin and Millais in Scotland, and it was at Acland's suggestion that Millais painted the well-known portrait of Ruskin, standing beside the torrent of Glenfinlas.

Ruskin's interest in the Oxford Museum, which was the outcome of Acland's reformative ideas about anatomy and physiology, is well known. He delivered lectures on it, and wrote pamphlets; he inspired the architects, gave money for its decoration, and himself designed a doorway.

In 1858 the Museum was in course of erec-

EAST END OF ST. MARY'S CHURCH, BIRKIN, YORKS.

tion, its architects being the late Sir Thomas Deane and Mr. Woodward, and its style Modern Gothic. On January 20th of the following year Ruskin wrote to Acland in reference to their unfulfilled hopes about the building. The following is an extract from the letter :—

"But farther—do you suppose Gothic decoration is an easy thing, or that it is to be carried out with a certainty of success at the first trial, under new and difficult conditions? The system of the Gothic decorations took eight hundred years to mature, gathering its power by undivided inheritance of traditional method, and unbroken accession of systematic power; from its culminating point in the Sainte Chapelle, it faded through four hundred years of splendid decline; now for two centuries it has lain dead—and more so—buried; and more than so, forgotten, as a dead man out of mind; do you expect to revive it out of those retorts and furnaces of yours, as the cloud spirit of the Arabian Sea rose from beneath the seals of Solomon? Perhaps I have been myself faultfully answerable for this too eager hope in your mind (as well as in that of others) by what I have urged so often respecting the duty of bringing out the power of subordinate workmen in decorative design. But do you think I meant workmen trained (or untrained) in the way that ours have been until lately, and then cast loose on a sudden, into unassisted contentions with unknown elements of style? I meant the precise contrary of this; I meant workmen as we have yet to create them: men inheriting the instincts of their craft through many generations, rigidly trained in every mechanical art that bears on their materials, and familiarised from infancy with every condition of their beautiful and perfect treatment; informed and refined in manhood, by constant observation of all natural fact and form; then classed, according to their proved capacities, in ordered companies, in which every man shall know his part, and take it calmly and without effort or doubt—indisputably well,—unaccusably accomplished—mailed and weaponed *cap-à-pie* for his place and function. Can you lay your hand on such men? or do you think that mere natural good-will and good-feeling can at once supply their place? Not so—and the more faithful and earnest the minds you have to deal with, the more careful you should be not to urge them towards fields of effort in which, too early committed, they can only be put to unserviceable defeat. Nor can you hope to accomplish by rule or system what cannot be done by individual taste."

Sir Henry Acland's memory is perpetuated by Ruskin in one of the most striking passages of "Præterita" (Vol. I., ch. xi.):—"Fortunately for me—beyond all words, fortunately—Henry Acland, by about a year and a-half my senior, at Christchurch chose *me*; saw what helpless possibilities were in me, and took me affectionately in hand. . . . He quietly showed me the manner of life of English youth of sense, good family, and enlarged education. . . . gave me the good of seeing a noble young English life in its purity, sagacity, honour, reckless daring, and happy piety. . . . Both in art and science he could pull me on, being years ahead of me, yet glad of my sympathy, for till I came he was literally alone in the University in caring for either. . . . The curious point in Acland's character was its early completeness. Already in these yet boyish days his judgment was unerring, his aims determined, his powers developed; and had he not, as time went on, been bound to the routine of professional work and satisfied in the serenity, not to say arrested by the interests, of a beautiful home life, it is no use thinking or saying what he might have been; those who know him best are the most thankful that he is what he is."

The First Batch of the 110 Artisans' Houses at Hornsey, erected by the Hornsey District Council, shows on the year's working a balance on the right side of £317, after paying £45 for repairs. A second batch is now in course of erection at Highgate, at rents varying from 7*s.* to 9*s.* a week. The smaller houses have four rooms and the larger have five, with a garden 60ft. long.

ITALIAN GARDENS.

A BEAUTIFUL villa in a fair landscape garden makes one of the most delightful scenes of the cultivated earth. This is only true if the garden be artistic, and unfortunately it is one of the rarest things in the world to find such a garden. To be really effective the artificial or formal garden requires to be laid out with the greatest possible care by an artist, and it is for this reason that the beautiful gardens of the Renaissance in Italy are so celebrated. For century after century Italy has produced artists who have given their serious attention to all the small matters of life as well as in the creation of palaces, statues, or great mural paintings.

The Italians were the initiators of the artistic movement of the Renaissance, and to-day these gardens are considered by modern landscape architects to be masterpieces. They are not only plantations destined to give shade and to assemble rare flowers, but were arranged to give a chance for a promenade. They afford a majestic decoration around a villa or château. Art is combined with nature to produce a most graceful and grandiose effect, and they were laid out with the true feeling for art. All of the gardens of the Renaissance in Italy were planned following a regular method, and this

THE RECTORY, BIRKIN, YORKS: SOUTH VIEW.

is not strange when we consider the architecture for which the garden served as a setting The architectural lines are strongly accentuated by the plantations. One finds in these gardens specimens very little altered of the best creations of the Renaissance. There are still the same disposition, the same ornamentation, and almost the same flora. The gardens of Italy present the rich and picturesque quality of modern gardens without their puerile simplicity. They are planted regularly around the villa, and it is always by an artistic progression that the house is reached. In the Italian gardens nature is assisted by art, and art is not used entirely in their creation. These gardens give exactly the same idea of country houses of which we hear so much from classic writers, as, for instance, Lucullus in the gardens of Sallust, the gardens of Pliny, Cicero, &c. They have their modern counterparts in those of the Villa Albani, Pamfili-Doria, the Aldrobrandini, &c.

If one studies the plans of these villas and those of the Barberini, Borghese, and d'Este, one will notice that the artists have not been dominated by the thought of making a symmetrical design, but that in adapting the lines of the plantations to the house itself, their principal object, they have largely concerned themselves with making use of the natural disposition of the ground as they find it, and devote a large part of their energies to achieving well-studied perspectives, intended to be viewed either from the house or from important points of the promenade. The design of the garden was not made solely with a view to the principal effect, for minor views were arranged for, but the grounds were laid out in such a manner that there were a number of interesting parts ably brought together so as to form a homogeneous design. Each detail is a picture sufficiently detached from the *ensemble* to be of value by itself. Each particular composition is justified by usage, and every work has its decorative quality which demonstrates its right to exist. Placed in well-chosen sites, nature has imposed few obstacles to the creation of a beautiful composition, and even furnishes the principal means for accomplishing remarkable effects. The great terraces shade those walking on stately promenades from the direct rays of the sun, and connect with one another by straight or circular paths. Broad staircases ornamented with balustrades, vases, and statues give a noble and elegant aspect to the gardens. Beautiful fountains are constantly playing, and the sparkling water contrasts with the green of the foliage. The beautiful parterres and avenues are usually provided with statues, arches, and columns. These decorations taken from architecture and sculpture seem entirely in place in Italian gardens, although they do not appear as much so in the gardens of the north, where the light is less intense and the climate less propitious.

It was not until the golden age of the Italian Renaissance, when architecture had well-nigh attained perfection, that new form was given to the principles which had once been embodied in the classic Roman villa. In many cases the villa itself and the gardens were designed by the same master, who was at once architect, landscape architect, and sculptor. The Italian gardens are constantly noted in the literature of the Renaissance, and even the scenes in Boccaccio's masterpiece are laid in an Italian garden in the environs of Florence. In some of them were scientific collections, such as botanical and zoological specimens, as in the parks of Lorenzo de Medici, the botanical collection being kept at the villa at Careggi, where he breathed his last, and the zoological collections at Poggio a Cajano. The greatest architects and sculptors did not feel that it was beneath their notice to devote great attention to such gardens.

Tivoli is an ideal spot for a villa, and this fact was fully realised by the Romans, for many of them, including Mæcenas and the Emperor Augustus, founded beautiful villas there. Under Hadrian the splendour of the place attained its climax, and in the Middle Ages it participated in the fate of Rome. The Villa d'Este is the masterpiece of Pirro Ligorio, and was originally begun by the

Bishop of Cordova. The quantity of water employed to adorn the grounds, and the variety of its treatment, show a reminiscence of the Moorish gardens of Spain. The villa is interesting architecturally on account of the ingenious construction of the terraces and the ramps which connect the palace with the gardens below it. The charm of the gardens is in their atmosphere and the mass of the grounds which is in shadow. At present the trees have grown to a great height, and the once trim hedges are no longer well kept, and the garden is an unkempt wilderness. The sound of trickling, splashing water, and the singing of the birds lend variety to the scene. From almost any part of the gardens can be obtained wonderful views of the Campagna. Unfortunately, access is now denied except to those who may be acquainted with its owner, who is a high ecclesiastic.

It is not only in the south that we have specimens of beautiful villas, but also in the north, as, for instance, in the splendid alley of trees and statues at a villa near Vincenza.

In the environs of Florence there are many fine villas. The Villa Reale di Castello is located in a beautiful park, and contains a fine fountain surmounted by a figure of Hercules. Unlike the Villa d'Este and the Roman gardens, water is not used in so much profusion: in Rome and Tivoli water was supplied in such vast quantities by the aqueducts that it could be used very freely. The Villa of Poggio a Cajano lies near Florence, and was built for Lorenzo the Magnificent by Giuliano da San Gallo in the simple rustic style. It is surrounded by a splendid old park, and commands a beautiful view of the mountains which surround the valley of the Arno. It was not always the case when the Italian gardens were laid out that terraces, fountains, and statues were the sole means of decoration; occasionally whole parks were left as nature had planned them.—"Scientific American" (Building Edition).

MAYBOLE CASTLE.

MAYBOLE, "the capital of Carrick," is a town of considerable architectural and archæological interest. At one time its streets were lined with "many pretty buildings belonging to the several gentry of the country," but now Maybole Castle is the only one left in anything like its original condition. The plan of the original building—it has been added to in later times—is a modification of the L-shaped plan so common in Scottish castles. The small arm of the L contains the stair, which in the upper floor blossoms out into the "bower" with the very fine oriel shown in the sketch of the castle from the south-west. This oriel—one of the few mediæval examples of this feature left in Scotland—is enriched with several heads, supposed by local authorities to be portraits of the actors in the story which forms the subject of the well-known ballad of the elopement of the wife of the sixth Earl of Casillis with a certain "Jonnie Faa." But, apart from tradition and myth, the castle with its unique oriel and "skew" with pierced gable-head, its quaint dormer windows and peculiarly Scottish chimneys and corbelling, is well worth the study of every architect. The drawings of the castle on this page are by Mr. J. Jeffrey Waddell.

A new Mission Church at Weston Green, Thames Ditton, is to be erected from plans by Mr. A. J. Style, architect.

THE WINDOWS OF ST. SAVIOUR'S, SOUTHWARK

AN INTERESTING SCHEME OF COMMEMORATION.

A CEREMONY which took place a short time ago at the ancient church of St. Marie Overie, or St. Saviour's, as it is usually styled, marked another stage in the original and broad-minded scheme of commemoration of by-gone worthies, inaugurated by Canon Thompson eight years ago, in the placing of stained-glass windows in the church to the memory of the goodly company of celebrated men who have lived or worked in this great Borough of Southwark. On the occasion in question, Dean Farrar unveiled the Bunyan window in the north aisle, a memorial to that inspired Non-conformist tinker whose great work ranks among our classics. This window to the author of the "Pilgrim's Progress" has appropriately been given by the children of the diocese of Rochester. It is an example of the liberal-minded view taken by Canon Thompson that Bunyan, the once persecuted of the Church, who officiated at Zoar Street Chapel, often in fear of again being cast into prison, should now find his apotheosis under the roof of the Establishment. He is but one of a varied company, forming a kind of abridged Positivist Calendar in stained glass, whose tardy memorials are rendering St. Saviour's a place of pilgrimage. It is nearly four years since the restored church, soon perhaps to be the Cathedral of a new Diocese of Southwark, was re-opened after the rebuilding of the great nave and the execution of other works, involving a total expenditure of £80,000. Since the beginning of that work of restoration fourteen commemorative windows have been installed, including the Bunyan window and the neighbouring one to Chaucer to be unveiled by the Poet Laureate on October 25th.

Beginning with the south window of the south transept, the gift of Sir Frederick Wigan, the subject is the Tree of Jesse. Like most of the series, it is by C. E. Kempe. Close by is the Newcomen Window, to the memory of one of Southwark's greatest benefactresses, Elizabeth Newcomen, buried in the church, November 20th, 1675. The Newcomen Charity and educational endowments are more than ever valuable. This window, a beautiful one of three lights, was unveiled by the Duke of Connaught in 1898. Another three-light window—the easternmost in the south aisle—is to Shakespeare and his brother Edmund, presented by Sir Frederick Wigan "to the glory of God and in gratitude for His good gift to men in the genius of William Shakespeare, 1564–1616, whose greatest works were mostly written while he was connected with and resident near the Globe Theatre, once standing on the banks of this parish, and whose brother Edmund, an actor, was buried in this church." Figures of Shakespeare and of Spenser are prominent in this window.

The next is one of a series of single lancet lights. This is to Philip Massinger, "buried as a stranger in this parish," 1639. The subject, taken from Massinger's play of the

"Virgin Martyr," represents St. Dorothea. The window to John Fletcher, who is also buried in the church, near his brother dramatist, comes next in order. The central panel, taken from his "Knight of Malta," shows the consecration of a knight of the Order of St. John. Another dramatist's memorial follows, in that to Francis Beaumont, 1586-1616, the collaborator with Fletcher. A symbolical figure of Friendship, with the armorial shields of the two poets, fills the centre. Next in succession westwards is a window to Edward Alleyne, "a player," one of the chief exponents of the drama in the age of the great Elizabethans. Much more, however, than a wearer of sock and buskin was Alleyne, for he was the founder of Dulwich College, and as such has his place here, in the memorial placed by the governors and old scholars of that flourishing foundation. The principal feature of it is a representation of Alleyne reading the charter and constitution of his "Colledge of God's Guift," in the presence of Lord Chancellor Bacon, Lord Arundel, Inigo Jones, and others. Alleyne lived longer than many of his contemporaries, who were remarkable both for the brilliance and the short span of their lives. He died, sixty years of age, in 1626. St. Paulinus, Bishop of Rochester from 633 to 644, occupies the next place. We now come to the west end of the church, with a window to Saint Swithun, Bishop of Winchester, from 852 to 862, and founder of this Collegiate Church.

The central three-light window of the west front is the finest in the building, and is appropriately seen down the whole length of the long vista of the church. It was designed by Henry Holliday in the Burne-Jones manner, and represents the Six Days of Creation, in a gorgeous glow of colour that as the summer sun enters the western sky flares and dazzles like a bonfire. The north aisle is as yet almost wholly a range of plain windows, all of them, however, allotted, and it is only a question of time when they will be filled. Two, as we have already seen—the Bunyan and the Chaucer windows—are ready. Chaucer, of course, has his place here by reason of his famous pilgrims starting hence for Canterbury. Those yet to come are to Oliver Goldsmith, who once practised as a physician on Bankside, in the parish; to Dr. Johnson, who lived for some years with the Thrales at their brewery in Park Street, where, by the way, his chair is still preserved by Barclay and Perkins; to Baxter, who officiated for some years in a place of worship on the site of Shakespeare's Globe Theatre; to Henry Sacheverell, chaplain of St. Saviour's, and a favourite preacher of Queen Anne's; and to Cruden, author of the familiar "Concordance to the Bible," buried in the parish.

A large window to the memory of the Prince Consort is in the north transept, and in the lady chapel, a recent one among the crude attempts of sixty years ago that afflict this part of the church. This rather curiously commemorates Charles the First and Archbishop Laud. Charles, it is not generally known, was a benefactor to the poor of Southwark, while Laud was a friend of Bishop Lancelot Andrewes, of Winchester, who lies here. The portraits of both King and Archbishop are very finely rendered. The remaining new window to be mentioned is that over the altar, given by Sir Frederick Wigan, a beautiful rendering of the Crucifixion. Funds are accumulating towards the making of the windows that yet remain blank, and so in a few years' time, what will soon, no doubt, be the cathedral of a new London diocese will be fully furnished with a series, handing down the memory of great men who have been connected in some way with South London.

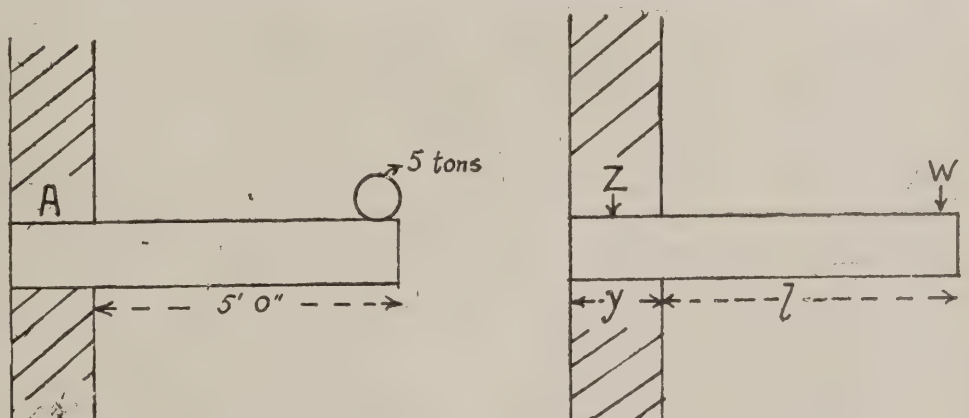
Machen Church, Newport, Mon., is being restored by Mr. C. B. Fowler, F.R.I.B.A., who has discovered on the west side of the chancel arch stone doorways leading to the rood loft. On sounding the wall on the south side of the chancel arch a niche, with a cusped head, was also found, filled in with boards and lath and plaster. The entrance to the rood loft is rather uncommon in this position. Generally it is constructed in the north wall of the nave. A similar niche on the north side of the chancel arch has been found.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Smoke Prevention.

CREDITION.—J. E. B. writes: "Can you advise me what method to adopt to prevent as far as possible a chimney discharging volumes of black smoke? The chimney is 45ft. high, the flue is 2ft. by 2ft. at the base, and is built for a 8 horse-power Cornish boiler. The smoke passes from the fire through the centre of the boiler, and returns under the boiler, thence to the chimney through a flue on each side of the boiler. The chimney is not strong enough to allow it to be built higher without taking down about 30ft. of it."



Increasing the height of the chimney will not improve matters, for the cause of the trouble lies in the fire-box of the boiler. If it is found impossible to fit a new fuel-feeding apparatus, a new boiler with such an apparatus will be necessary. In one of these the fuel is thrown on to a kind of sieve which is moved to and fro, dropping the fuel over the fire. Several such appliances for smoke consumption are on the market.

Counterbalance of Cantilever.

LLANELLY.—A. E. E. writes: "I would be greatly obliged for detail information on the following:—

$$A = \frac{2 \times 5 \times 5}{3} = 16\tfrac{2}{3} \text{ Tons.}$$

How does Mr. Middleton make the above equal to his alternative method? $Z \times \frac{y}{2} = W \times l$."

COUNTERBALANCE OF CANTILEVER.

They are not equal. The load A being evenly distributed acts at the centre of the wall, and therefore $A = \frac{2 \times 5 \times 5}{1\frac{1}{2}}$.

G. A. T. M.

Materials for Brass Rubbings.

WARWICK.—C. M. C. A. writes: "Are there any special materials supplied for taking brass rubbings, and if so, from whom may they be obtained? Otherwise, I suppose ordinary full-size detail paper and heelball will answer."

The best heelball is made by Mr. Francis Ullathorne, 7 & 9 Gate Street, Lincoln's Inn Fields, price 6d. and 1s. a piece. A composition known as a brass-rubber, giving an exact facsimile, is also used, but I am unable to say whence it may be obtained. Black lead and oil, or black lead (the ordinary stove lead) and paper—the first has the objection of being a very dirty process. As to paper, ordinary white, 20½in., is good enough, but the quality should be thin.

ANDREW OLIVER.

R.I.B.A. Final Examination.

LLANELLY.—A. E. E. writes: "Could I enter for final examination of the R.I.B.A. if I were a member of the Society of Architects by examination? I have heard that the latter does away with the preliminary and intermediate examinations of the former society."

Any architect in practice for himself, and over 25 years of age, may be admitted to the final R.I.B.A. examinations without first passing the intermediate or preliminary, but the Society of Architects' examinations are not acknowledged.

G. A. T. M.

The Royal Academy Schools.

LONDON, N.E.—STUDENT writes: "A short time ago you published particulars of the work for admission as a student of the Royal Academy Schools. One of the drawings required to be done at the Royal Academy by the probationer is to be 'a geometric elevation (with or without a plan) of some building, or some part of a building, in London, to be done from the probationer's own notes, and measurements taken from the building itself.' Does this mean that the probationer has to select his own subject in London and measure it before the time of the examination, or that the examiners will select the subject to be measured? If the former should be the case, could you give me any idea of the kind of subject they require?"

The probationer has to select his own subject in London, but he need not necessarily measure it before the examination; he may do so two or three days after being admitted. Any Renaissance doorway would do as a subject—say, that of St. Martin's Church. It would be well for querist if he went down to the Academy School and saw Mr. Pheané Spiers, the master.

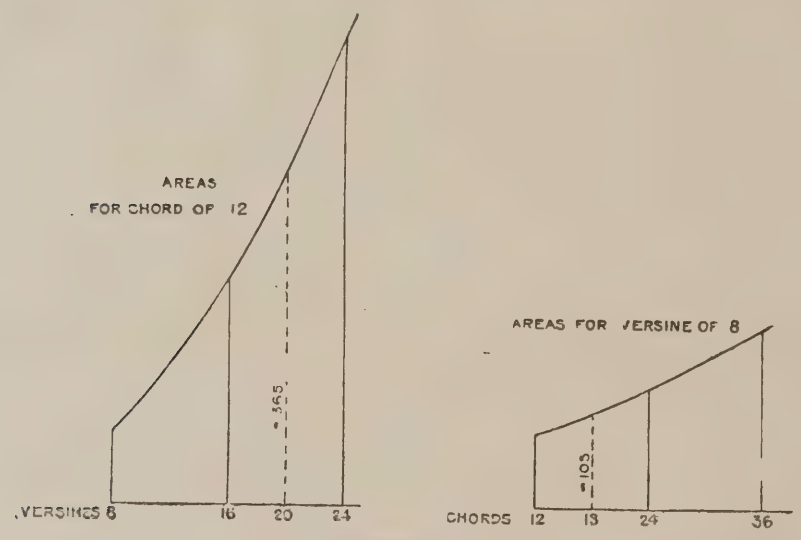
A Question of Frontage.

LONDON, N.—F. B. writes: "X has a house, built three years ago, on a road which may be called A. Z, the opposite owner, is now building a house with its back to X's front, having acquired all the land between the road A and another road, B, running parallel 200ft. away. Should the local authority approve such a plan under the Local Government Board's model by-laws; and, if so, under which by-law? Or is X's remedy (if any) a civil one, his value being depreciated by the unexpected and objectionable outlook? There is only 10ft. set back from road A: the by-laws require 20ft. at the *back*, but Z insists that his *front* faces the road A, although his W.C.'s and offices face this road and his entrance and bays the road B."

It does not appear that the local authority could refuse to sanction the plan merely because the front elevation is unsightly, and Z is within his rights in calling that his front which is built to the general frontage line in road A. It is doubtful if querist has any remedy.

G. H. B.

Law Lettering.



BOLTON.—ENGROSSER writes: "Kindly recommend some books from which to study and practise Old English or other lettering

required for law purposes. Which are the better to use, pens or quills?"

There are many copy-books to be obtained showing the various styles of lettering—Egyptian, Roman, Old English, French, &c. Some may be purchased for sixpence. Then there is Mr. Lewis Day's book, "Alphabets, Old and New" (B. T. Batsford, 94 High Holborn, W.C., price 3s. 6d. nett), which should be of great use. Many law-writers use quills—it is a matter of individual preference—but good work can be done with a broad steel pen. Before parchment can be written upon, it must be pounced with cuttlefish powder, which can be bought at any law stationer's. Ordinary engrossing is done with a special nib having a long, fairly wide point.

Area of Segment of Circle.

STONEHOUSE, DEVON. — ASSISTANT SURVEYOR writes: "Is it possible to find a formula for a curve giving the areas of circular segments of constant chord, but varying versines, plotted on a base denoting versines, the ordinates giving the areas? Of course the curve may be obtained roughly by calculating the area for each separate versine, but this would be very tedious and laborious."

AREA OF SEGMENT OF CIRCLE.

The simplest formula for area of segment of circle is the following:—

$$A = \frac{4}{3}v \sqrt{\left(\frac{5}{8}v\right)^2 + \left(\frac{1}{2}s\right)^2}$$

where A = area, v = versine or rise, s = span or chord. By making a few calculations, covering the range required, the areas for constant chord or constant versine can be plotted as ordinates to a curve, and any intermediate area can then be scaled from the curve. Suppose, for instance, the chords taken be 12, 24, and 36, and the versines be 8, 16, and 24, the areas will be:—

Versines.	Chords.		
	12	24	36
8	83·31	138·67	199·25
16	248·75	333·23	439·25
24	516·15	614·72	749·76

and any row either vertical or horizontal can be plotted (see figures) to obtain intermediate values. A single curve cannot be made to do duty with two variable quantities, as the case involves the use of a curved surface instead of simple curve, and there is no means of plotting a curved surface. HENRY ADAMS.

Examinations in Building Construction.

CASTLE DOUGLAS. — OUT OF THE WAY writes: "I should like to pass some examinations in building construction. I am 934 miles from London, and it is improbable I will be any nearer for some time. May I think of entering for them under these circumstances? I am eighteen years of age."

It would be best to write to the secretary of the Science and Art Department, South Kensington, S.W., asking for particulars of the examinations in building construction, the location of the nearest examination centre to Castle Douglas, and all further particulars as to date of examination and fee charged for entry. The examinations are usually held on the first Saturday in May of each year. Anyone is eligible to sit. G. A. T. M.

Plaster Casts of Vases.

NOTTINGHAM. — DECORATOR writes: "How are fibrous plaster casts of vases and flower-boxes made? Where can I purchase models?"

Vases and flower-boxes composed of fibrous plaster are unsuitable for their proper use, i.e., rearing or keeping plants or flowers, in the open air, and are only used for theatrical purposes or house decorations, similar to artificial plants, flowers, &c. Vases and flower-boxes to resist the effects of weather, wet and soil are generally composed of artificial stone. Terra-cotta, also cast-iron, is sometimes used in the manufacture of vases, and similar wares. Plaster piece moulds are used for casting fibrous plaster casts of vases and flower-boxes, also for casting artificial or Portland cement vases, and for pressing terra-cotta casts. The moulds are seasoned and oiled, then gauged plaster is brushed over the surface, and then canvas is laid on and brushed over with plaster until the whole surface is covered. This operation of brushing plaster and canvas is repeated, and when the plaster is set the mould is taken off, and the seams on the cast cleaned off, thus completing the cast. Flower-boxes are made in a similar way. Models of vases and flower-boxes can be purchased from W. Millar, No. 1 and 3 Arch, Brighton Terrace, Battersea Park Station, London. W. M.

A Municipal Engineering Text-book.

BRIGHOUSE.—J. T. L. writes: "Can you te l me the best book or work to get for municipal training for a youth who has served a few years in an architect's office?"

"Municipal and Sanitary Engineer's Handbook," by H. Percy Boulnois, M.I.C.E, 15s.; published by E. and T. N. Spon, 125 Strand, W.C.

Rules for Setting-out Stairs.

LONDON, S.W.—A. P. writes: "Do the rules given in 'Rivington' and similar works for width of treads and heights of risers of stairs include the projection of nosing?"

Although the nose forms part of the tread, it should be ignored when setting out the staircase, and only the going from riser face to riser face set up on the drawing, the nosing being added afterwards. The proportion of treads to risers should be:—

Width of tread.	Height of riser.
7in.	8in.
8in.	7½in. to 8in.
9in.	7in. to 7½in.
10in.	6½in. to 7in.
11in.	6in. to 6½in.
12in.	5½in. to 6in.
13in.	5in. to 5½in.
14in.	4½in. to 5in.
15in.	4in. to 4½in.

J. W.

Welsh National Eisteddfod: Competitions.

KETTERING.—C. H. writes: "I should be glad to have particulars of the Welsh National Eisteddfod subjects for design, referred to in a recent issue. Where can I obtain them?"

The Welsh Eisteddfod for 1901 is to be held at Merthyr Tydfil, and a local committee has been, or will be, formed to arrange all the business in connection with the subjects of competitions, &c. The subjects are generally announced in a pamphlet at the close of the year preceding the Eisteddfod, and are obtained from the secretary, who will be able to give any further information. I regret I have been unable to obtain the name of the Merthyr Tydfil secretary. The designs, &c., for the various competitions are usually sent in before the 12th or 13th of August, and the Eisteddfod is held in September each year, when the awards are made. R. W. O.

Section of Column or Stanchion.

CHORLEY.—A. B. C. writes: "If you were given the weight to be carried by a column or stanchion, the length, and the safe weight per square inch, how would you find what section to use?"

If the safe load per square inch be given it is a simple matter to find by trial what section to adopt. For example, a hollow cast-iron column 12in. diameter to carry 60 tons, where the safe load is 2 tons per sq. in. $\frac{60}{2} = 30$ sq. ins. required. By reference to table, 12in. diameter = 113 sq. in. area, $113 - 30 = 83$ sq. in. $= 10\frac{1}{4}$ inside diameter. $12 - 10\frac{1}{4} = 1\frac{3}{4}$, $1\frac{3}{4} \div 2 = \frac{7}{8}$ thickness of metal. If the section is to be solid of + form, a trial section must be made to see if the area is sufficient and altered accordingly. It is, however, very unusual for the safe stress to be given, as that depends upon the ratio of diameter to length. For full method of calculating and designing see "The Practical Designing of Structural Ironwork" (Spon 8s. 6d.)

HENRY ADAMS.

Colouring Portland Cement Red.

LONDON, N.W.—A. G. S. writes: "What is used for colouring Portland cement red without affecting the stability of material?"

Portland cement can be coloured red by mixing it with a red oxide. The quantity of oxide to be added to the cement depends upon the strength of the oxide, as some are much stronger than others. Five per cent. of a strong oxide will impart a close resemblance of the desired colour to the work, but a weak oxide will require from 10 to 15 per cent., and even 20 per cent., to obtain the same colour. Some of the red oxides range in colour from scarlet or Turkey red, gradually deepening to chocolate. The oxide should be intimately mixed with the cement in a dry state before it is gauged. For cast work the coloured cement should only be used for the brushing coat and then backed up with the natural coloured cement and aggregate. For plastered work the coloured cement should only be used for the fining coat. The use of a good oxide and proper manipulation will not deteriorate in colour or effect the stability of the work. Another method for colouring Portland cement work, with or without sand, is effected by brushing over the surface, while it is moist or semi-dry, with a solution of alum mixed with oxide.

W. MILLAR.

The Parish Church of Weston Turville, Buckinghamshire, which was about 700 years old, has just undergone extensive restoration. In 1861, when the church was reseated, many coloured pieces of glass were discovered under the floor, and they were inserted in the windows nearest to which they were found, proving that this church was one of the many that suffered desecration during the days of the Civil War. It is hoped to refill the windows with stained glass in the near future. A list of the patrons of the living and the rectors from the year 1264 to the present time is exhibited in the nave, and shields bearing the coats-of-arms of various patrons and persons hitherto connected with the church have just been places in the chancel roof. The church now possessed a magnificent organ.

LONDON COUNTY COUNCIL.

At last week's meeting of the London County Council, the General Purposes Committee reported that the solicitor had informed them that the contract for the purchase at the price of £20,000 of the fee simple of No. 17 Fleet Street, subject to an existing lease and an arrangement for a renewal of it, had been exchanged, and that completion was to take place on or before December 24th next. On July 31st they reported upon a claim made by the vendors for £1,349 for expenses and liabilities paid or incurred in pulling down the back and side walls and rebuilding a portion of the party wall, and in respect of architect's and surveyor's fees and charges for plans of the rebuilding. That claim had now been waived except as regards the sum of £165 16s., which they asked might be refunded, and they supported their request by the statement that the amount was included in the estimate of the Council's architect for the cost of rebuilding. When the matter came before the Council on March 27th the sum of £7,000 for "rebuilding the back and restoring the front of the building" was included in the total estimate of £27,300 in connection with the cost of acquisition and restoration of the premises, and, as indicated in the report on July 31st, the sum of £7,000 covered a "moiety (£165 16s.) of the party wall at back." It was a fact, therefore, that the sum in question, although not specifically mentioned in the report in March last, was included in the original estimate, and should in the circumstances be paid to the vendor as part of the £7,000 authorised for the rebuilding. As the solicitor had asked for definite directions, they had given instructions to him for the completion of the purchase to be at once proceeded with, and for the request as regards the payment of the sum of £165 16s. to be acceded to. They recommended that the course taken should be approved. This was agreed to.

Colonel Rotton observed that it was ridiculous nonsense to pay £27,000 for sentiment.

The recommendations of the Improvements Committee with reference to the exhibition at the gallery of the Royal Society of Painters in Water Colours, at 5A Pall Mall East, of the suggested designs for the Holborn-Strand elevations (see page 222 of last week's issue) were agreed to. The Committee was authorised to spend a sum not exceeding £52 10s. in obtaining expert advice upon the designs in question.

The same Committee also reported that the Council upon their recommendation agreed on July 4th and October 10th, 1899, to contribute one-half of the nett cost of the widening of the portion of Mansell Street within the City boundary, and of the southern end of Middlesex Street, proposed to be undertaken by the Corporation from time to time as opportunity occurred. The estimated nett cost of this improvement of the northern approach to the Tower Bridge was £105,500. The Corporation had now submitted for the Council's approval an amended plan showing an improved line of widening in Middlesex Street. They approved the amended plan, and recommended "that, notwithstanding any previous resolution of the Council, the amended plan submitted by the City Corporation, showing a modified line of widening for Middlesex Street at Nos. 1 to 7 (odd numbers), and at the Essex public-house, be approved." The report was passed.

The Improvements Committee also submitted estimates of the gross and nett cost of ten proposed improvements (not including the Westminster improvement, the nett cost of which is estimated at £586,000), as follows:—Mare Street, Hackney, £660,750 gross and £576,100 nett cost, after deducting recoupment by sale of surplus land; Goswell Road, £227,800 gross and £209,500 nett; St. John Street, Clerkenwell, £92,400 gross and £79,400 nett; Blackstock Road, Islington, £5,200 gross and nett; Archway Road, Islington, £6,000 gross and nett; Kentish Town Road, £10,450 gross and nett; Nine Elms Lane, £171,300 gross and £160,300 nett; Battersea Rise, £46,900 gross and £43,900 nett; Blackheath Road, Blackheath Hill, and New Road, £41,200 gross and £39,700 nett; High Street and Gardener's Lane, Putney, £45,030 gross and £37,430 nett—total, £1,307,030 gross and £1,167,980 nett.

The Committee asked the Council to approve the gross amounts, because they might have to be expended before any recoupment was obtained.

The report was adjourned in order that the financial aspect of the estimates might be considered by the Finance Committee.

Engineering Notes.

The London County Council Tramways show a profit of £54,847 for the year ending March 31st last.

New Dock at Llanelly.—In order to complete the new dock at Llanelly the sum of £144,000 is required.

Mr. W. P. Adams, M.I.E.E., of 35 Queen Victoria Street, E.C., has been appointed consulting electrical engineer to the Borough of Heywood.

Proposed Tramway in Tottenham Court Road.—The Vestry of St. Marylebone has decided to refuse its sanction to the proposal of the London County Council to lay a tramway along Tottenham Court Road.

Proposed Electric Tramways at Oldham.—A Local Government Board enquiry was held last week into the application of the Oldham Corporation for power to borrow £280,000 for electric tramways in the borough.

New Dock for Swansea.—The Swansea Harbour Trust executive have decided on a site eastward of Lambert's works for the new dock. The site will afford water space of 54 acres, and the project, it is estimated, will involve the outlay of a million and a half sterling.

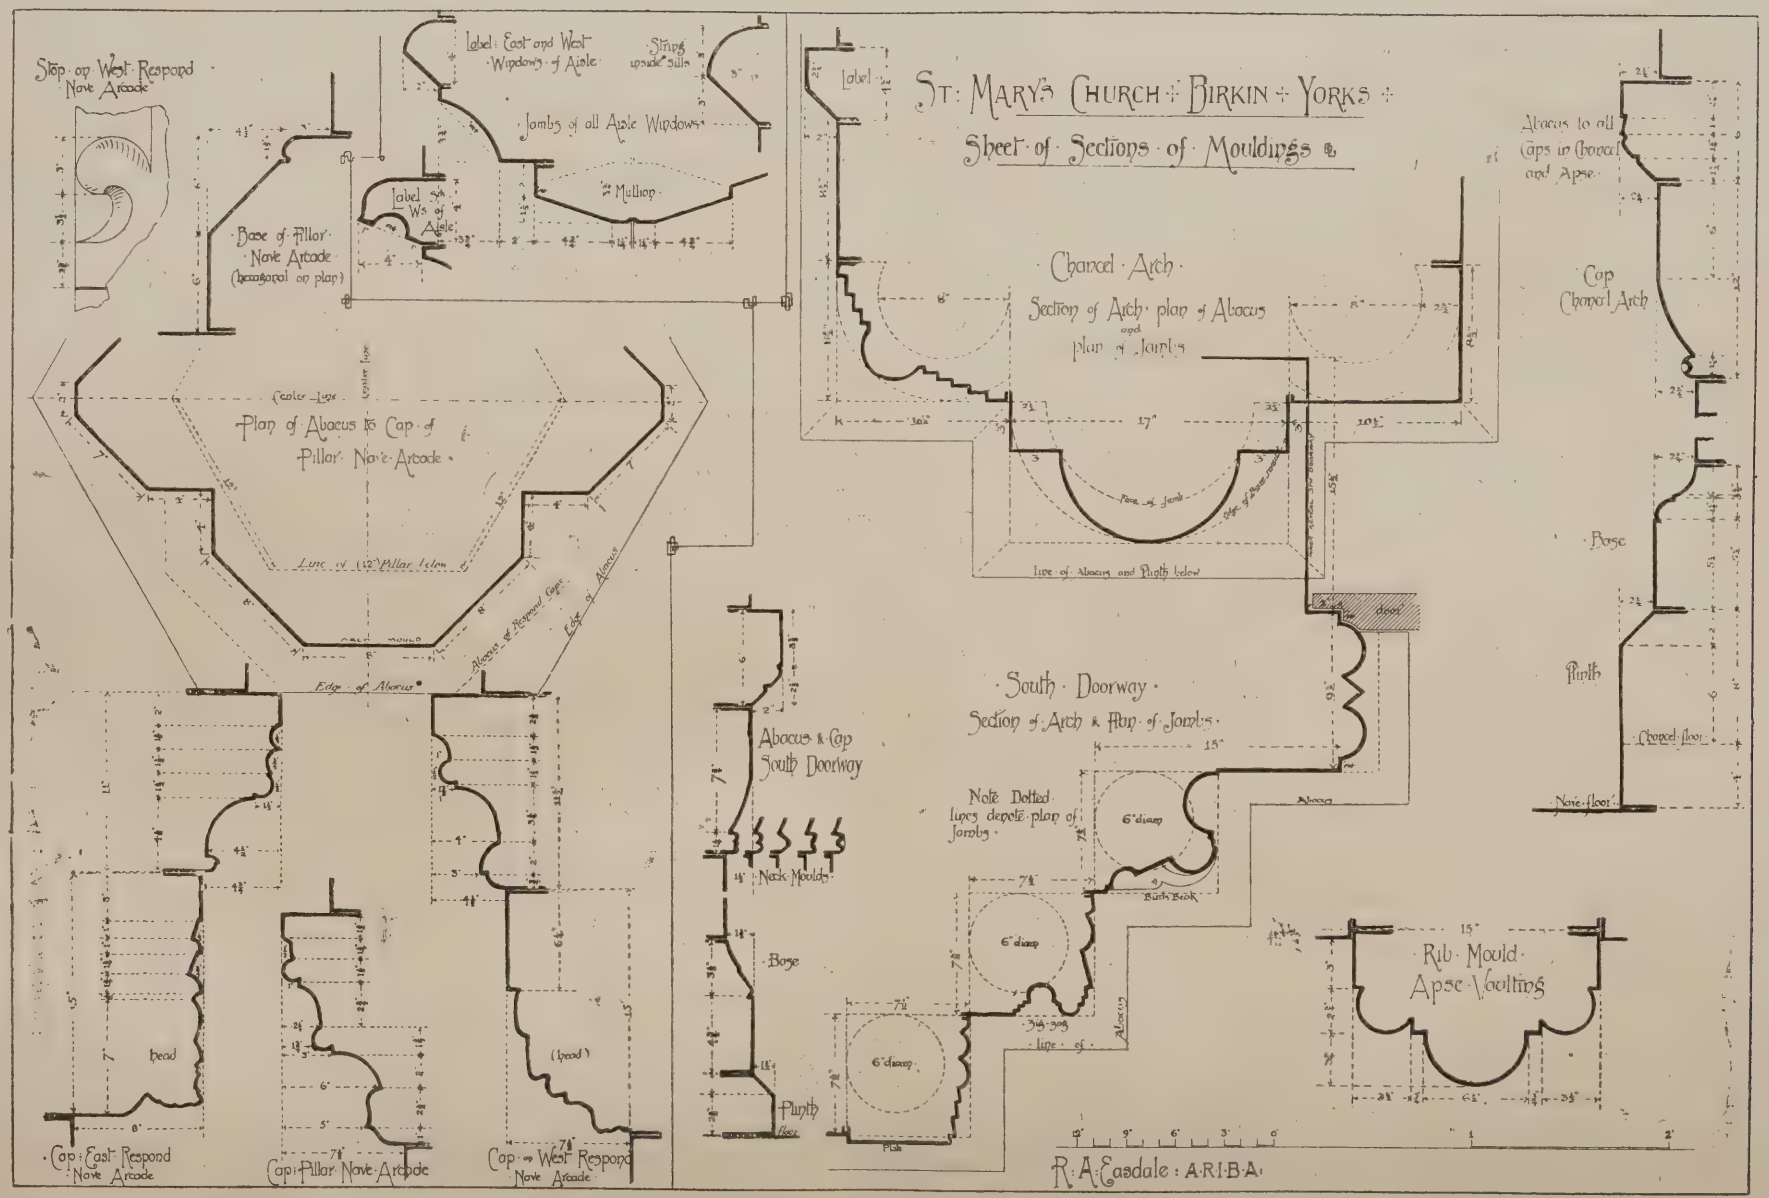
Heating of the County Hall, Wakefield.—Mr. Rivers, heating engineer, having inspected the County Hall, Wakefield, and given it as his opinion that the best course would be to thoroughly revise the heating system, rather than to attempt to patch up the present defects, the tender of Messrs. Ashwell and Nesbitt for carrying out the improvements at a cost of £1,245 was accepted at the last meeting of the West Riding County Council.

Transmission of Electricity.—The well-known Niagara Falls installation for the generation of electricity is, as regards distance of transmission, eclipsed by a company which supplies Los Angeles (California) with electricity generated at a distance of 83 miles away. Even this, however, is to be rendered insignificant by the plant now being built which will convey to San Francisco electricity which has been generated 145 miles away. This, it need hardly be said, will be the greatest feat hitherto accomplished in electrical transmission: 60,000 volts will be thus supplied generating 14,000 horse-power, or enough to run the street railway system of San Francisco with a good surplus for factories.

Proposed Tramways for Leigh.—The following recommendations of the Tramway Committee have been approved by the Leigh Town Council:—That the town clerk, borough surveyor, and electrical engineer be instructed to report upon the advisability of the corporation (1) constructing and working tramways; (2) constructing tramways and letting them on lease; (3) permitting a company to construct and work tramways within the borough; that the town clerk be instructed to request the South Lancashire Tramways Company, in pursuance of the South Lancashire Tramways Act, 1900, to widen St. Helens Road and King Street, the east and west sides of the north and south approaches to Leigh Bridge, and Leigh Road.

A new Rival of the Arc Light.—At the junction of Wellington Street with the Strand six new street lamps have been erected by Messrs. W. Sugg & Co. for the Strand Board of Works. By them Messrs. Sugg claim to be able to supply a light superior to an electric arc lamp at half the cost. The advantages claimed for the new burner are that it gets about ten times the light out of the same number of cubic feet of gas. This is obtained by sending the gas through the burners by means of a hydraulic ram, which increases the ordinary pressure in the gas main about four and a half times. The gas passes through a small burner of steatine, an incorrodible stone, and is then impinged by diagonally placed outlets upon a Sunlight burner. The velocity with which the gas passes through the burner carries with it a volume of air, and the two mixed burn with an intense white light.

Electric Trams for High Wycombe.—An important scheme for the establishment of electric tramways was considered on Tuesday in last week by the Wycombe Town Council. The scheme provides for the laying of lines from the eastern boundary of the borough to the western, a distance of four miles. The Council approved the scheme, and it is probable that it will soon be carried out.

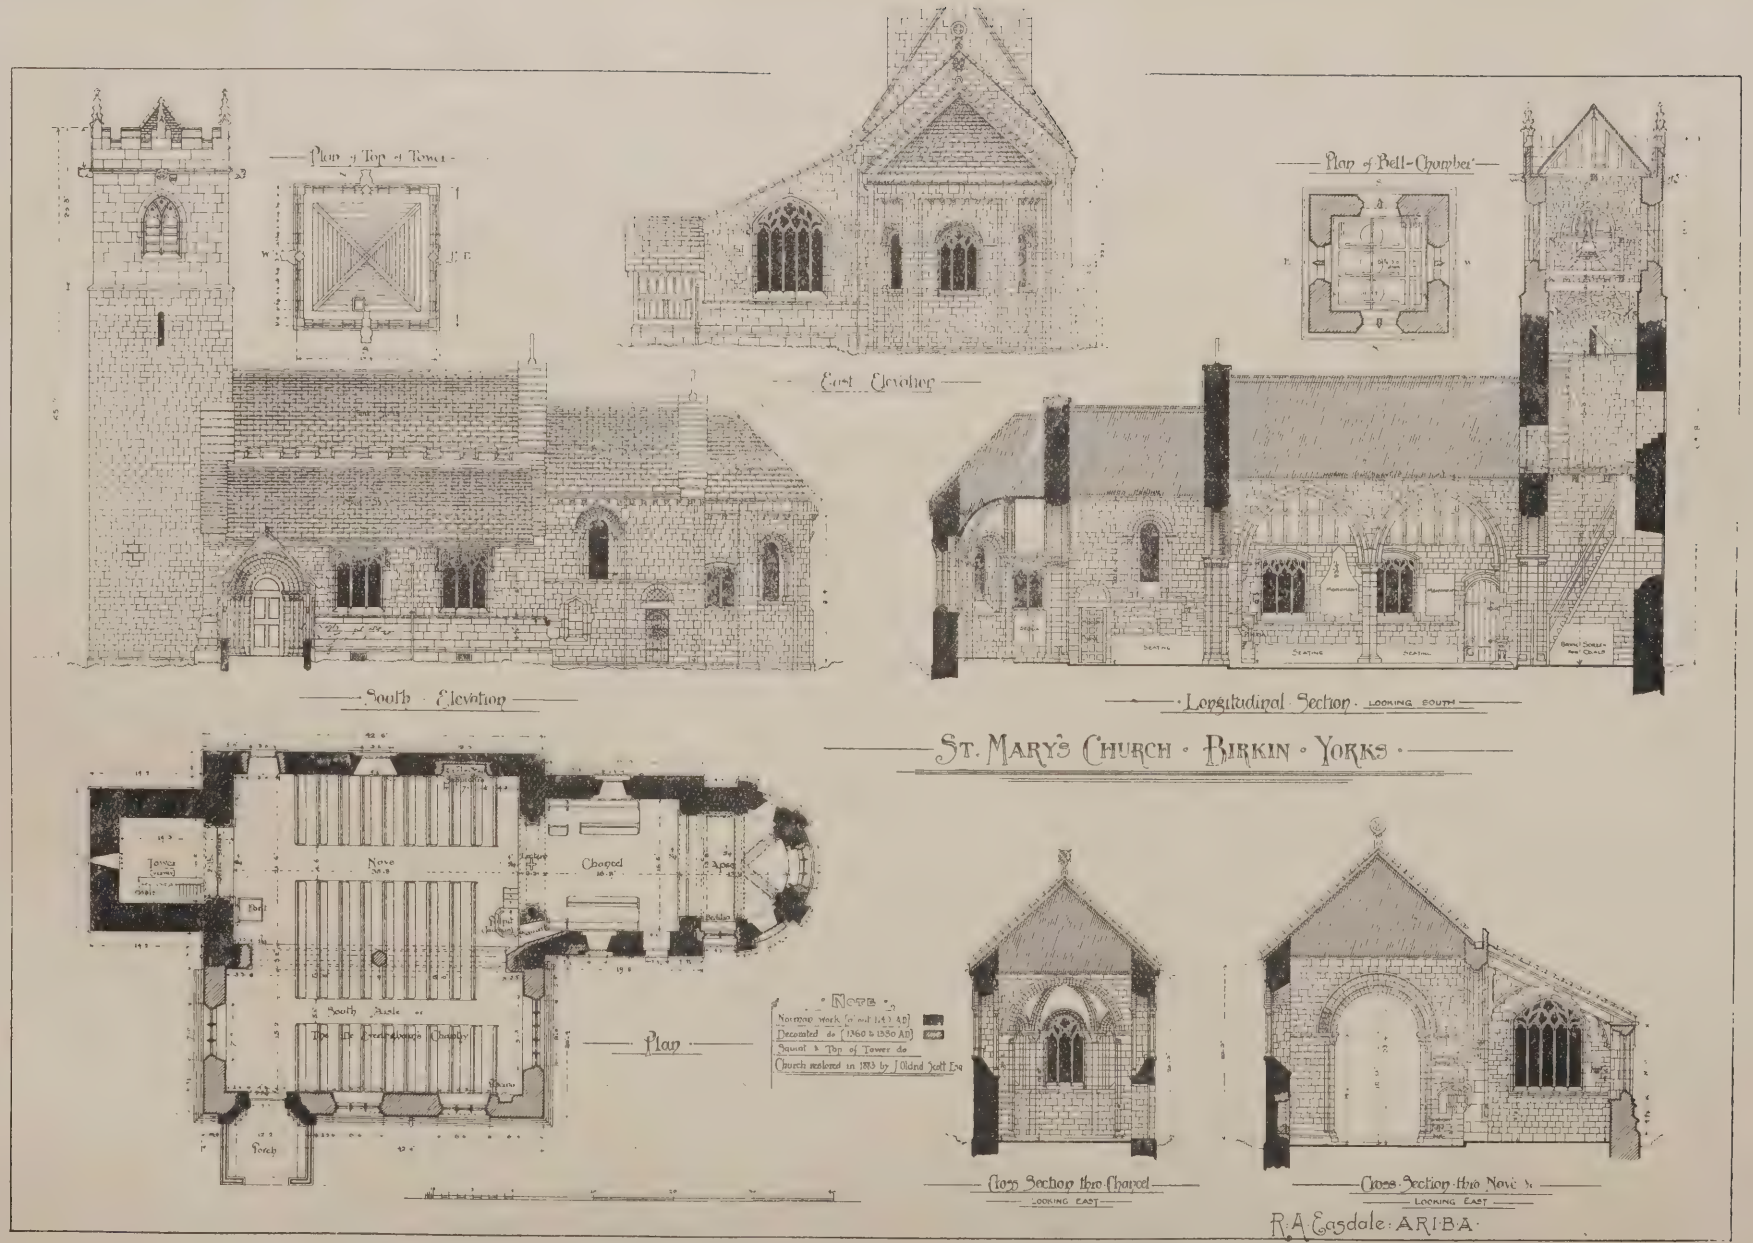


Hackney's New Electricity Works. — On Thursday last Mr. Alderman Dickinson, L.C.C., laid the foundation stone of the new electricity works in Millfields Road, Hackney Like its neighbour, Shoreditch, Hackney is associating with its electric light and power works a refuse destructor. The buildings are to be erected on a site of about five acres, with a frontage on the Lea River Canal. The engine-house alone will be 130ft. by 50ft. The chimney shaft will be carried up to a height of 200ft., and, according to Mr. Robert Hammond, the engineer, has been specially designed as an ornament to the neighbourhood. The amount of horse-power which it is proposed to erect plant for will be about 3,000; and this, with accumulators, is expected to supply sufficient current for about 50,000 glow lamps of the usual 8 candle-power type. Room, however, is to be left for increasing the horse-power to 6,000. Arrangements have been made for the erection of 320 arc lamps, and cables of a total length of 100 miles are being laid down in the streets and roads. The refuse destructor will consist of twelve furnace cells, capable of burning 150 tons of refuse a day; and as far as is possible this will be automatically handled—as at Shoreditch.

Masters and Men.

The Bricklayers' Strike at Newcastle-on-Tyne and Gateshead, which has existed since May last, now threatens to eventuate in a general lock-out in the building trade of the North of England. A large and influential meeting of the Master Builders' Federation was held last week at Newcastle to consider the position, and it was resolved to endorse the action of the Federation in arranging for a lock-out from November 3 in the Northern Counties if the dispute be not settled by that date. If the employers' resolution be carried out it will affect the joiners, masons, slaters, plumbers and painters, in addition to the bricklayers. The demand of the bricklayers is for an advance of 1d. per hour, from 10d. to 11d.; and the employers have offered to refer the matter to arbitration, or to guarantee the present rate of wages for the next two years.

Trade in September.—The Board of Trade report that in the engineering and metal trades employment during September has remained fairly good. Employment in the building trades has remained good in most branches; the percentage of unemployed Union members among carpenters and plumbers at the end of September was 2·1, compared with 1·8 in July and August. In the furnishing trades employment has fallen off. Twenty-nine fresh disputes occurred in September, 1900, involving 6,032 workpeople. Of these disputes five occurred in the building trades, six in the mining and quarrying industries, and six in the metal, engineering and shipbuilding trades. Changes in the rates of wages of 164,199 workpeople were reported during September, making a nett increase of about 2s. 1½d. per head.



The new Church of St. Barnabas, Grimsby, was dedicated recently. The new church has cost £2,500, and has seating accommodation for 420. It is in style a simple version of the Romanesque. The bell gable at the west end is 75ft. above the roadway. The inside measurements are 98ft. long by 43ft. wide and 32ft. high.

Correspondence.

Houses of Strange Design.

To the Editor of THE BUILDERS' JOURNAL.

EXETER.

SIR,—Apropos the house planned like the ace of clubs, it may interest "J. W." to have some particulars of the building erected by Sir Thomas Tresham, about 300 years ago, near Rushton, in Northamptonshire. It may be thus described:—The house is all threes, each of its three sides being exactly 33ft. 4in.—that is 33⅓ft.—in length. There are three storeys. Each has three windows on each of the three sides, and each of the windows in two of the three storeys is in the shape of the trefoil—the three-leaved shamrock. The panes of glass are all triangles, or three-sided. In each of the other windows there are twelve panes of glass in three fours. There are three gables on each side rising from the eaves; and from the centre, where the roofs meet, rises a three-sided pyramid, terminating in a large trefoil. The smoke escapes from this chimney by three round holes on each of the three sides. On the top of each gable is a three-sided pyramid covered with a trefoil. The building is almost covered with inscriptions and carving, three Latin inscriptions, one on each of the three sides, having 33 letters in each. Three angles on each side bear shields. Over the door is a Latin inscription of three words, meaning, "There are three that bear record." Inside the house each corner is cut off from each of the three main rooms, so that on each floor there are three three-sided apartments. I have visited the building in question more than once, and consider it, from every point of view, extremely ugly.—Yours truly, HARRY HEMS.

Builders' Notes.

The Late Mr. Augustus Bird, of Eynham Lodge, Wood Lane, Shepherd's Bush, builder and brickmaker, who died on April 13, left property valued at £177,909 8s. 2d., of which the nett personalty is £68,999 9s. 11d.

The Death of Mr. James Barrow, builder, of Beech Road, Cale Green, Stockport, occurred last week. The deceased gentleman, who was 38 years of age, was very well known in the district. He was stepson of Mr. Henry Wild, builder, of Hillgate, with whom he lived, and had the management of his stepfather's business.

The Aberdeen granite firms have for many years imported upwards of 10,000 tons of foreign granite, mainly from Norway and Sweden. To supplement the local supply granite firms are now directing attention to County Donegal, which has literally miles upon miles of granite formation that only requires to be developed. The quality will compare with any imported, and the supply is practically unlimited. It is to be hoped as a result of the visit of the prospectors that the quarrying industry of the North of Ireland will be opened up on an extensive scale.

The Sheffield Building Trade continues to slacken, and the boom which prevailed up to a couple of months ago has now quite disappeared. Although there has been no such utter collapse there as is reported from other large centres of population, the failures of speculative builders have occasioned heavy financial losses to firms who supply timber, stone, slates, bricks, hardware, and other requisites of the trade. The check to building operations has not been brought about because the demand for houses is satisfied, but solely because, on account of the dearness of all kinds of materials, houses do not now provide a profitable investment for capital. Cottage houses are still scarce. Instead of keeping lists of vacant dwellings the agents have on hand lists of applicants who are waiting patiently for a vacancy. The decline in trade has appreciably relieved the scarcity of labour which had become so acute as to cause serious inconvenience and loss. Never before have the men engaged in building operations earned so much money as during the past spring and summer.

Fire Tests with Partitions.—We have received from the British Fire Prevention Committee No. 52 of their publications, giving the result of a test with a partition formed with "Mack" patent slabs, and erected by Messrs. J. A. King and Co., of London. The slabs used in the partition were 2⅜in. thick, and were made of plaster, with cocoa-nut fibre, cork dust and reeds embedded in it: the partition was plastered, and was 10ft. by 7ft. 5in. Three weeks (spring) were allowed for construction and drying. The following is a summary of the effect:—The setting coat on the fire side of the partition fell whilst heat was being applied. Part of the rendering on the fire side fell when water was applied. The fire did not pass through the partition. On the passage side no effects were apparent, with the exception of two blisters, and some hair cracks following the courses of the joints. The temperature of the outside face of the partition at no time exceeded 125° F. The plastering on the inner face of the partition was cracked and disintegrated. Upon examination after the test the face of the slabs next to the fire were found to be disintegrated for a depth of about ¾in., but the remainder was unaffected.

A Builder and the Halifax Building By-Laws. At a monthly meeting of the Halifax Rural District Council it was reported that Mr. G. Frankland, of Sowerby Bridge, had pulled down two houses at Norland to the level of the road and rebuilt one house on the site without having submitted proper plans. In doing this, Mr. Frankland had committed an offence and was liable to have his house pulled down or to a penalty. The Surveyor (Mr. F. Gordon) said that he had informed Mr. Frankland that what he suggested would be contrary to the by-laws. Councillor Whittaker remarked that there were complaints that no improvement took place at Norland, but the moment a man made an improvement the Council objected on the ground of some formality or other. The only fault to be found with this building was that there was not sufficient air space behind it, owing to the proximity of an old building at the rear of it. It was a paltry piece of business, and the Council ought to be ashamed of themselves that they did not accept this man's improvement. He had submitted two plans. The Chairman said that proper plans, accompanied by particulars, were necessary, and those had not been sent in in this case. Mr. Gordon said that the new building was undoubtedly an improvement on the old one. Councillor Sykes remarked that they ought to adhere to the by-laws; for if they let one man escape, others might take advantage. Councillor Mitchell: "If the building is an improvement, I should say pass it over. I propose that." Councillor Whittaker seconded the motion, which was carried.

A Suggestion for Builders.—It is indeed remarkable to note that in these days of progress so little is done in certain branches of the building trade to supply material on the job ready for use. It is true that, in the large blocks of buildings which are now and again erected in the larger cities, machinery is put down for making mortar for elevating the various portions of the building to their position; but in the erection of smaller houses practically everything is done on the job, excepting the joinery work, which is usually bought ready-made, and sometimes the carving of the stonework, should there be any. In Philadelphia, some years ago, a company was formed to supply mortar, and it was very successful. The mortar was made of the best materials in large quantities, and with most effective mixing machinery, and was delivered in specially-constructed carts to any parts of the city, the cost being not a little less than that which the builder would have to pay if he mixed the mortar himself. Now, says "Oils, Colours, and Drysalteries," why could not the same thing be done on a modified scale in connection with paint? "We do not now advocate the use of so-called ready-mixed paints, but by way of example we will suppose that a builder is erecting 50 houses of the suburban-villa class in lots of 10. He knows exactly the paint he will want for priming and the subsequent colour-coats. Instead of mixing them himself, at considerable expense and labour, why should he not go to a paint manufacturer and get exactly the same thing delivered to him already mixed just in the quantities he wants? He would certainly save money, and he would assuredly get as good a paint, or better. He could ask for an estimate on a paint made exactly as he would make it, and the profit would come to the manufacturer, and the lessening of price to him because of the facility with which the large quantity of paint could be mixed with machinery, contrasted with the mixing by hand. The idea is certainly well worth the careful consideration of up-to-date builders."

Mr. W. A. Shepheard, builder, of 16 Meadow Road, South Lambeth, died last week.

Strange Building Trade Failures at Bradford. At the Bradford County Court last week, before Mr. Registrar Lee, Arthur Ellis, of Hemsworth, and John Thomas Ellis, of Hull, recently trading under the style of Ellis Bros., builders, of Bradford, came up for public examination. The Official Receiver reported that the debtors began business as builders in Bradford without capital in April, 1899. Mr. F. U. Laycock, solicitor, of Bradford, made advances to them, and they commenced to build three separate lots of property successively, and did not complete any of these lots owing to Mr. Laycock's refusal to continue assistance, the work being then given by the solicitor to other builders. A private meeting of the creditors was held four months ago, and certain offers were made and not accepted. Mr. Arthur Ellis, in answer to questions put, said a Mr. Beale came to his brother and himself on behalf of Mr. Laycock, and said that if these two could borrow money from somebody else to carry buildings to a certain height Mr. Laycock and he would help them with further money They began on fifteen houses in Norman Lane, Eccleshill, on Mr. Laycock's land. They borrowed £10 from someone else to start building, and afterwards got certain moneys from that gentleman, and went on for nearly a year. Then they were told to start a job in Bowling in order to "hold Norman Lane up." He did not know how the holding-up of Norman Lane was to be done by getting into debt somewhere else, but those were their instructions, and further money was refused them unless they did so. A third lot of buildings was afterwards started in the same way, and in connection with the three they got goods of various kinds from different unsecured creditors to the amount of £800, scarcely any of these goods being paid for. Mr. Laycock had now taken possession of the whole of these properties. The reason that Mr. Laycock gave to him for taking the work from him was that he wished to keep the creditors off it. The result was that there was now nothing whatever to pay their creditors with. When the meeting of their creditors was held, three or four months since, Mr. Laycock offered to find for the creditors 4s. in the pound on the debts of the Norman Lane property if he and his brother would find 1s. Mr. Laycock also offered to find 7s. 6d. in the pound for their creditors in relation to the Bowling property. These offers were refused. From the commencement Mr. Laycock had financed them, and had financed others in a similar way who were all bankrupt like himself. He had been pressed on account of Mr. Laycock's cheques being dishonoured. He had kept promising him payments and not making them. When Mr. Laycock made his offer to his creditors it was not accepted at first, but before he had withdrawn the offer it was accepted by the only one who had stood out. He was now working at Hemsworth for 10d. an hour. Mr. J. T. Ellis stated that he agreed with his brother's answers; he was working at Hull for £1 19s. a week. The examination was closed.—Samuel Wilson and William Grundy, builders, of Norman Lane and Stonehall Street, Eccleshill, also came up for examination. It was stated that they had begun business eighteen months ago without capital, and had also passed through the hands of Mr. Laycock, under somewhat similar circumstances. The examination was closed.

Bricks and Mortar.

Aphorism for the Week.

The best architecture is the expression of the mind of manhood by the hands of childhood.

Ruskin.

Our Plates. The measured drawings of Birkin Church, by Mr. R. A. Easdale, A.R.I.B.A., form part of the illustrations to the article on this very interesting old building which begins on page 225 of the present issue.

Newcastle Town Hall. In connection with the proposal to erect a new town hall at Newcastle-on-Tyne, a writer in the "Newcastle Journal" points out that it is not for a moment to be denied that there is need for a good public hall for musical performances and other purposes. But to raise such a building is not within the province of a Corporation; and a Municipal Council that should stand in the way of private enterprise in this direction would be acting undutifully to the public. The building of the existing town hall, in respect of site, style, and accommodation was a crying blunder. It was the product of a temporary and unreasoning craze for such buildings, and was achieved in the teeth of the best architectural advice of the day, including that of the architectural reformer of Newcastle, the celebrated John Dobson.

A Liverpool Scheme. It is proposed at Liverpool to form a new street 70ft. wide from Bath Street to Leeds Street. The estimated cost is for buildings and easements £130,000, and for paving £8,000, or, say, roughly £140,000; and considering its utility, the scheme is cheap. Liverpool has been laid out without any sort of system or plan, with the result that there is insufficient access between the city and the line of docks. There are very few large thoroughfares; most of the important streets lead to nowhere. Although the line of thoroughfares parallel with the docks is very good to the north and to the south, it is very bad in the centre. The Goree, New Quay, and Bath Street are narrow guts. The memorial to the Corporation which has resulted in the present scheme was signed by about 250 important firms and associations. To a great extent the diversion of traffic from the line of docks through the city has been due to difficult gradients. The streets between the docks and Old Hall and Great Howard Streets are too steep for heavy traffic, but the proposed new thoroughfare, being cut in a lateral direction, will present an easy gradient of 1 in 55. The effect of this improvement will be to relieve the thoroughfares round the Exchange of a large part of what is strictly dock traffic; it will reduce the cost of maintaining those thoroughfares, and obviate delays in the electric tram service, which is every month swelling to more and more enormous proportions. Indirectly, the improvement will increase the necessity for widening Bath Street, New Quay, and the Goree. In regard to the last, everybody is agreed that this ancient and obstructive eyesore ought to become a thing of memory as soon as possible.

Badly-Framed By-Laws. Three years ago new building by-laws were accepted for Scarborough, and ever since very serious complaints have been made by the local builders and architects with regard to the working of these by-laws. It was found that the Corporation were enforcing restrictions which were not enforced in many other boroughs in the country, and, furthermore, with regard to timber sizes the Corporation adopted measurements which were outside all sizes stocked in Hull and Grimsby. Consequently it was found by builders that in order to come within the by-laws the cost of building property in the borough became excessive, and no doubt this retarded the building of many houses in the borough during the past two years. When the facts were known, the Council unanimously agreed to appoint a committee to consider the whole matter, and see whether the mistake—for all now admitted it was a mistake—could not be remedied. Now, at the last meeting of the Town Council, after eighteen months, the Committee recommended the adoption of the amended by-laws which the Local Government Board have approved. This was agreed to, so that the Scarborough builders will henceforth go about with a light heart.

Aylesford Bridge. Aylesford is situated upon the Medway, about half-way between Rochester and Maidstone, in charming country, and has the good fortune to have escaped most of the modern disfigurements which have quite changed the rural characteristics of most English villages. There are an old church and some old gabled cottages, but by far the most interesting object is the fine fourteenth century bridge, with its Gothic arches. This, says the "Daily Graphic," is now declared to be "inconvenient," and will probably be pulled down, unless some vigorous protest is made against such an act. The Society for the Protection of Ancient Buildings has put forward a plan which would not only obviate all inconvenience, but would save the fine old bridge and greatly improve the navigation of the river. The suggestion consists of making a "cutting" about 300 yards up the river. This will again fall into the river below stream, creating an island between the village and the railway, and forming a bow, of which the old river would be the arc, and the new "cutting" the "string." As the "string" would be almost straight (following the line of the railway), it would be a great help to navigation. In a line with the old bridge, a road would cross the island raised upon a causeway, connecting it with a new bridge over the cutting, and prolonged across the railway so as to replace the present dangerous and inconvenient level crossing. The old bridge would be increased in width by the addition of wooden footways 4ft. wide, supported upon timber staging, such as may be seen on many old bridges on the Continent. There appears to be no special difficulty in carrying out this scheme, while the advantages are obvious—especially to those who know the locality.

Changes at the G.P.O. The announcement that the old General Post Office, to the east side of St. Martin's-le-Grand, is to be demolished and rebuilt will remind antiquaries that this site was associated with the intimate daily life of Londoners so far back as the Norman age. The collegiate church of St. Martin's-le-Grand led all the other City churches in the nightly ringing of the Curfew; it being expressly ordained that the tolling of its great bell was to be the signal to every parish church, "so that they begin together and end together." The building now doomed was authorised by Parliament in the year of Waterloo, and was erected from the designs of Sir Robert Smirke. Previously the Post Office had sought accommodation in several parts of the City, including the ignoble region of Cloak Lane, Dowgate Hill. It was only when Lombard Street and Abchurch Lane threatened to burst under its expansion that the removal to St. Martin's took place. A leader dealing with the old and new post-office buildings appeared in The Builders' Journal for May 16th last.

Foundation Stones. Foundation-stone discoveries, says the "Globe," are usually unexpected, but none the less delightful. In February last there was some excitement in Paris, when the Palace of Industry was demolished, everyone engaged being eager to discover the foundation stone of the building, which was erected in 1855; for it is known to contain a casket in which repose papers of that date, various moneys and a document bearing the autographs of the third Napoleon and the only Baron Haussmann, who practically rebuilt the French capital. Some day, perhaps, like the long-lost foundation stone of the Cour des Comptes, these records will be unearthed, but so far, we believe, they are yet to be found, and will probably rest undisturbed until Paris is furnished with a twenty centime "tube," when they may turn up in the excavations, or when the new Palaces of Fine Arts are pulled or burned down years hence. For the benefit of antiquarians of the next century it is stated that when the foundation stone of the Children's Hospital at Norwich was laid, certain papers, coins, &c., were sealed up in a specially-prepared cavity. There is a brass plate, with the date and following inscription on it:—"Norwich population, 113,000. Fastest train to London, 2 hours 37 minutes. Electric tramways commenced. Price of large sheep 63s. Bricklayers' wages, 7½d. per hour." The "fastest train" paragraph will doubtless provoke mirth in that age of rapid travelling, when people will be forwarded by wireless telegraphy.

A Clerestory Window. At the church of St. Bartholomew the Great, Smithfield, a hidden clerestory window is now to be utilised. Its date appears to be about the year 1190, but when the brick tower was built in 1628 on the outside the window was bricked in, remaining hidden, though not forgotten, until the present time. It has now been decided to re-add it to the features of this interesting church, and, in order that as much light as possible may be obtained from it, the glass to be used will be plain and clear. In

any case not much light can be obtained from it owing to the close proximity of the tower; but, now that the brickwork which filled it in has been removed, it is seen that there will be sufficient light to note the design of the church floor. This window consists of two plain lights, an unadorned circle, and probably what is known as plate tracery. It is a much earlier window than those in the choir, which were all rebuilt in the fourteenth century. The window has already attracted great attention from the many visitors to St. Bartholomew's, and the authorities, naturally, are not a little proud of possessing what is undoubtedly one of the few existent specimens of the earliest architecture.

Liverpool Cathedral. THE proposal to erect a cathedral at Liverpool has been revived by Archdeacon Madden. He considers that the site in London Road is "ruled out" of consideration by the circumstance that £500,000 would be required, though, he says, "it is only the price of one ironclad and less than one half-year's drink bill for the city. There are fifty men in the diocese who could put down £10,000 each and die happier and richer men because of their gift to Almighty God." He turns with reluctance to consider what many would call the more practical scheme. This is the site of the cathedral church of St. Peter, which has advantages from the utilitarian if not the architect's standpoint. Archdeacon Madden says: "The site will probably be a gift. The patronage of the parish of Liverpool is now in the hands of the Gladstone family. When we remember that at his last visit to his native city Mr. Gladstone made an eloquent appeal for a cathedral, it is almost certain that his sons would be prepared to further their father's wishes by helping forward a cathedral scheme as far as is possible for them so to do. The site is central, and we are told it is possible to build upon it a cathedral church at a cost of £100,000 to seat 3,000 worshippers. I think it possible to build a stately cathedral on a ground area whose total frontage is 340ft., and whose width is 200ft. The limitations of the site make a noble Gothic building impossible. Belfast churchmen in building their new cathedral, limited to the space on which their parish church was situated, have accepted the advice of Sir Thomas Drew, and have chosen the Byzantine and discarded Gothic design. The total length of the Belfast Cathedral is 214ft., and total width 88ft., and there will be room for 4,000 worshippers. A building of equal size and similar design could be placed on the Liverpool parish church site for £100,000, while a Gothic church would probably cost twice that sum." The Archdeacon adds that one who has made cathedrals a life study has suggested as the best design for a twentieth century cathedral "a Romanesque style and a Basilica ground plan, because more suitable to modern needs and capable of a good auditorium for some 3,000 people." The Archdeacon has no preference for any particular site or design, but he wishes Liverpool men to see that a cathedral is possible and practicable. In our issue for April 4th last we published Mr. William Emerson's design for Liverpool Cathedral.

The Royal Exchange Frescoes. ON November 6th two new frescoes for the decoration of the Ambulatory of the Royal Exchange are to be unveiled by the Lord Mayor. The fact that a woman artist has been entrusted with part of the decoration of one of our chief public buildings is probably without precedent, and there is certainly no instance on record of a husband and wife working together on a task of such importance. The subjects chosen by Mr. Ernest Normand and his wife—known in the world of art as Miss Henrietta Rae—for the huge wall pictures they have just completed are both connected in some degree with the past history of the City. Mrs. Normand, in the picture commissioned by Mr. A. Bailey, shows one of the most famous of the City's mayors distributing alms during a time of famine to his starving fellow-townsfolk. In "Sir Richard Whittington's Charities" the hero of so many legends is seen, a picturesque figure in scarlet robes and sables standing on the snow-covered steps of his house, supported by his Mayoress, Dame Alice, and her little daughter, both richly attired. To the left foreground is a huge brazier, filled with burning logs, and surrounded by destitute Londoners; in the centre a ragged child stretches up her arms to receive alms from the Mayor's little daughter, and on the right a stalwart retainer, in red hose and jerkin, distributes to the starving crowd the bread with which he is laden. In the background is an ancient City street, with roofs and chimneys covered with snow. Mr. Normand's picture (the gift to the City of Mr. John Paddon) illustrates "King John Granting Magna Charta." The scene is laid in front of the Royal pavilion in the meadow near Runnymede, with the red standard of England, emblazoned with golden lions, floating across the blue June sky. Great care has been taken by the artist to ascertain (through the Society of Antiquaries) the correct heraldry of each individual, and in choosing the costumes and the accessories. The new pictures, which are each about 18ft. high, will be permanently affixed to the walls of the Royal Exchange by the same method employed in the case of those painted by Lord Leighton, Mr. Seymour Lucas, R.A., and the other artists who have taken part in the decoration of the building.

Discovery of a Buried House at Naples. THE excavations carried on by the De Prisco family at Bosco Real, near Naples, which not long ago led to the discovery of some magnificent frescoes of the Pompeian epoch, have proved even more fruitful than was hoped. A huge country house completely buried has been found. No objects, ornaments, nor traces of furniture have been brought to light, but in compensation all the walls are covered with splendid frescoes dating from the time of the later Roman Republic, which, from their state of preservation and the freshness of their colours, might have been painted yesterday. Some of the figures represented are twice life-size, a circumstance specially notable because hitherto no frescoes in the Pompeian style have been discovered of more than natural dimensions. Three of the paintings are particularly beautiful, one representing a guitar player, a second an old gladiator apparently telling the story of his exploits to a woman, and a third a female figure listening entranced to the sound of distant music. Not only these figures but the walls of the house have been carefully removed in order that the house may be reconstructed. It is reported that the German Emperor is negotiating for the purchase of the whole structure, but it is doubtful whether the Italian Government would permit its exportation. A Government commission has been dispatched to Bosco Reale to examine and report on the discoveries.

House and Church Designs. THE two drawings on the previous page, of a house and boathouse and a hill church, are printed on account of their novel, and to some extent decorative, manner of depicting architecture.

Electric Fittings for Bridgewater Houes, London, the town residence of the Earl of Ellesmere, recently formed the subject of competition among a number of leading manufacturers in England and France. Over a hundred designs were sent in, those submitted by Messrs. Donnison, Berlyn, Sillem and Co., of London and Liverpool, being selected, and the order placed with them. These fittings consist of massive circular dishes of elaborately cut glass, 24in. in diameter, surmounted by finely designed metal coronas, these forming the principal part of each electrolier. The coronas of wrought and chased metal are in the style of the Italian Renaissance, in keeping with the decoration of Bridgewater House. In each case the coronas, with their six crystal pendants surrounding the larger central cut-glass dish, and carrying 45 lights in all, are supported by chains and rings from metal crowns at the ceiling above. The state rooms alone will take 16 of these electroliers, and the scheme is throughout of the most costly description.

THE KING'S BASTION, PORTSMOUTH.

THE destruction of the ancient fortifications of Portsmouth forms the subject of an invective by the "Times" newspaper. Of the five complete bastions and one demi-bastion, with the usual advanced works, ravelins, and counterguards, only one bit now remains—namely, the "King's Bastion," with its counter-guard in front, called the "Spur Redoubt," or, more properly, the "Spur Battery." All the rest has gone. It has been demolished at one time or another to make way for more modern defences or to enlarge the boundaries of a growing town. The "King's Bastion" is the very centre of endless historic associations, and its grassy slopes and picturesque masonry relieve a landscape which is otherwise monotonously flat. All this is now condemned, and the "King's Bastion" and "Spur Battery" will shortly fall a prey to the military contractor. The last remnants of historic defensive interest will then have disappeared.

The history of this bastion is well known. In the time of Elizabeth it had not yet been built. The fine masonry walls are in excellent repair, but the bastion and the spur are no longer used as defensive works. The bastion was formerly called "Wimbledon's Bastion," and did not receive its present title until King George the Third walked into it one fine day after inspecting his victualling yard close by.

Some years ago the site of the "Spur Battery" was offered by the military authorities to the Corporation of the town, but the offer was for some reason declined. Probably it was accompanied by conditions which would have necessitated the removal of the battery itself; for the acquisition of so unique a specimen of ancient and beautiful fortification could not have failed to prove a source of the greatest interest to residents and visitors. The value of the relic as a work of art alone, as a specimen of a lost art, should be enough to preserve it; but to this must be added a long roll of historic associations and the exquisite beauty of the scene as the sun sets behind Haslar in streaks of gold and red or clouds of purple splendour.

To-day the destructive hand of the military engineer is laid upon the work of his own forerunners; upon work which proves the genius of those who came before him, and which they and he have preserved for three hundred years with tender solicitude. Surely a strong and imperative motive should be advanced for the sanction of such an act of vandalism. Vital necessities, such as those of Imperial defence, may sanction any act. But here the motive is of little importance. A few tons of earth are required to complete a new battery lately erected in the vicinity, and they can be obtained more cheaply by the destruction of these ancient works than by any other means. Another reason has been more lately urged for the demolition of the beautiful "Spur Battery," namely, that it interferes with the fire of guns lately mounted. This is true to a certain extent, but it is only true because these guns have been placed in a position which they ought never to occupy. The remedy lies, not in the demolition of the old work, but in the utilisation of it. For the destruction of the "King's Bastion" there is not the shadow of an excuse.

In England there are few examples of the beautiful art of Vauban and Coehorn, for the art never flourished with us, and such examples as we once had have gone, just as the old walls of Portsmouth have gone, and for similar reasons. That little which remains is worthy of the attention of the Society of Antiquaries, a society which has more than once stayed the ruthless hand of the destroyer in this very town. It is therefore no mere local interest which demands the preservation of these ancient works, but a national interest. A stroke of the pen may save them; a stroke of the pen may sweep them away.

Memorial Tablets to Sir William Molesworth and Sir Austen Layard have been placed in St. George's Library, Borough Road, Southwark. They are life-size bronze portraits, and have been executed by Mr. George Frampton, A.R.A.

Surveying and Sanitary Notes.

Mr. Edward A. Harman, M.Inst.C.E., engineer to the County Borough of Huddersfield Gas Department, was duly elected a member of the Sanitary Institute at the last meeting of the council. Mr. Harman has done a considerable amount of work in connection with the disposal of sewage. Recently he made several interesting experiments with the sludge, obtaining therefrom illuminating gas to the amount of about 6,000 cubic feet of 13 candle-power per ton of material used, the material containing 28 per cent. of moisture.

Gas from Sewage Works.—A novel experiment is being made at Chorley. It has been conceived that the sludge from sewage purification works constructed on the principle of those at Chorley, owing to the oil and vegetable matter it contained, was rich in gas, and it has been thought possible that the material of this kind at Common Bank may be turned to profitable account as an illuminating agency. Consequently, a laboratory has been fitted up at the works. The gas gives a very brilliant light. Experiments on an extensive scale are in progress at the Corporation Gasworks, under the direction of the manager, Mr. J. McCubbin, who up to the present has demonstrated that 4,000 cubic feet of gas of 20-candle illuminating power can be produced from 1 ton of the sludge. So far, the experiments have been confined to small quantities of the sludge, and it has yet to be determined whether similar results can be produced from the material in bulk. Another problem to be solved is whether, supposing this latter difficulty is got over, the economic results will be such as to warrant the use of the sludge as a substitute for coal, or as supplementary thereto. Besides this, it has yet to be ascertained whether its odoriferous properties will operate against its general adoption, either as an independent supply or as a mixture with coal gas. If further experiments show that no serious hindrance to its use arises on those grounds, no difficulty will be experienced in utilising it, as no separate plant will be necessary, for it can be dealt with by the present retorts and clarifying apparatus, and admitted to the holders now in use. If the experiments prove successful, it would mean a considerable saving in the cost of the sewage works, as the sludge is now disposed of to farmers at the low rate of about 1s. per ton.

Street Improvements in Sheffield.—The City Council has sanctioned a scheme of street improvement, the great importance of which has for some years been clearly apparent. The streets leading to the Victoria Station are admittedly far too narrow for the traffic which passes over them, at certain times during the day the traffic along Furnival Road being very heavy. The next city Bill promoted will include clauses empowering not the widening of a single street, but the making of two entirely new streets, which will converge at the foot of the station approach and will give access to the railway from two points in the centre of the city. One of the new streets will begin at the junction of Exchange Street, Waingate, the Haymarket and Castle Street—at the Royal Hotel corner, in fact. That hotel will come down, and the street will run, in a straight line (its direction almost making it a continuation of Castle Street, as it is to be when widened), to where Blonk Street and the Victoria Station approach join. The street will be 70ft. wide. The second part of the scheme is the continuation of Bridge Street. The street is to be almost entirely carved out of that large market area known as the "killing shambles," which is at present in a most insanitary condition. Practically all the land between the two new streets already belongs to the Corporation, and the effect of making broad roads through an area that is at present almost inaccessible, or only to be reached by narrow lanes, will naturally be very beneficial. The improvement will also have the effect of clearing away a good deal of slum property at the back of Exchange Street and Furnival Road. The nett cost of the improvements is estimated at £75,000.

A COUNTRY HOUSE ELECTRIC-LIGHT INSTALLATION.

BY K. S. MACKINLAY.

THIS article is written to give architects, who have hitherto not given the subject much consideration, an idea of the requirements and approximate cost of a country house installation.

As the whole arrangement of an electric-light installation depends upon the number of lights required, a start may be made in one of two ways. Either a rough allowance may be made for each room, or the position, if not the nature, of each fitting may be fixed throughout the house. To obtain the best results the latter way is preferable; the former applies more in such a case as that of an architect who is designing a building which is to have an electric-lighting plant, and must therefore arrange for the space to be occupied by the engines, accumulators, &c. The number of lights having been settled, the next thing to be considered is the kind of motive power to be employed to drive the dynamo. If there is water-power that can be conveniently utilised, of course this affords the cheapest working, though the initial outlay is in some cases more; otherwise, if the installation is a large one, steam is the most practicable; if moderately large, there is the option of a gas or oil-engine plant. For small installations the choice is practically between these latter, and depends principally upon the price of gas in the neighbourhood; a small steam plant is quite practicable in this case, but it requires constant attention, which is, as a rule, undesirable in small installations.

I have here taken a country house as an example for a small installation, and have arranged for 75 lights, rather the maximum than the minimum number that would usually be required in a house of this size.

More than 40 of these would rarely be burning at one time, and if allowed for as 16-candle power 60-watt lamps, a battery capable of discharging 25 amperes at 100 volts for about six hours would be necessary. (100 *is the most convenient voltage for small or moderate-sized installations under ordinary circumstances.*)

There are many excellent types of accumulators on the market; I have taken here a battery of the "D. P. Battery Co.'s" cells which will answer my purpose, and are certainly as good as any. These are made in various sizes, of which the battery capable of discharging 25 amperes for six hours will fulfil the above requirements.

For supplying current at 100 volts fifty-three of these cells are required, and a current of 18 amperes is necessary to charge them. A dynamo giving 20 amperes is, therefore, very suitable for working with such a battery, and should be shunt-wound for 135 volts.

By running the dynamo in conjunction with the battery (when fully charged), the total number of lamps could be kept burning for six hours, or rather more. Where no accumulators are employed a 105-volt compound-wound dynamo would be used. A dynamo giving (20 amperes at 135 volts) 2,700 watts, which is 3·61 horse-power, would require a 4 or 5 break-horse power engine to drive it (the distance between the centres of the engine flywheel and the dynamo pulley must be $2\frac{1}{2}$ times the diameter of the flywheel).

ELEVATION OF ENGINE HOUSE.

In this example I have taken an oil-engine plant, and have shown an engine-house built, say, 40 or 50 yards from, and in a similar style to, the house.

The engine-room is 17ft. 6in. by 8ft., the accumulator room 13ft. 3in. by 6ft. $4\frac{1}{2}$in., and the building being thus only about 15ft. wide would not dominate its surroundings in an undesirable way, but, on the contrary, with a few trees or a shrubbery planted in front of it, it need not look in any way ugly or inartistic. I have shown an elevation to give some idea of what the general effect might be.

The engine and dynamo are indicated at A and B respectively, having a drive of 11ft.

The engine is fixed by Lewis bolts to a concrete bed, the dynamo to a wooden bed, or stand, and fixed in its turn to the concrete. The wooden bed is to insulate the dynamo from "earth," in accordance with fire-insurance requirements.

All gas and oil engines require a circulation

of water through the cylinder to keep it cool; a galvanised iron tank is used to supply this. One of these of the requisite size is shown at C; it is supported by planks, which rest upon brick piers, and is connected to the cylinder by a pipe, D, which is fixed at a slight incline. As the heated water passes out by this pipe the cooler water from the bottom part of the tank flows into the cylinder by the pipe E, which is laid immediately under the concrete floor. The cock at F is for emptying the cylinder and pipes when the plant is not working, lest the water in cold weather should freeze in the pipes and cylinder, and thereby burst them (of course, it is necessary to empty the tank, and the stop-cock G must be shut off before opening the cock F).

The bad gases, caused by the explosions of the oil, are carried through a pipe, H, and may be disposed of in various ways. Different firms have their own ideas as to the best method of treating the exhaust. The switchboard I have shown in detail to a larger scale. For lighting the engine-room I have indicated three pendants and a wall plug for a hand lamp.

As the fumes of sulphuric acid which are given off by the accumulators are deleterious to metal, this should be used as little as possible; and where the engine-room adjoins the battery room it is convenient to have a fixed window between the two rooms. I have shown two of these.

The fifty-three accumulators are arranged on two tier stands along each side of the room, twenty-two on the M side, eleven on the upper, and eleven on the lower tier, and on the N side sixteen above and fifteen below, thirty-one in all.

Where the plant is being put into an existing building, and there is large battery-room accommodation, single-tier stands would afford perhaps greater convenience, but in other cases these double-tier stands serve all practical purposes, and reduce the necessary size of the room by one-half. As the acid fumes would cause the wood to rot after a very short time, the stands should be treated with anti-sulphuric enamel.

A portable voltmeter for taking the voltage of each cell, and a hydrometer for testing the strength of the acid, though not fixtures, are indispensable accessories.

To light the accumulator room I have indicated two pendants and a wall plug for a hand lamp.

The seven lights in the engine-house form a circuit. I have not indicated a light in the porch, as I have shown doors with glass panels.

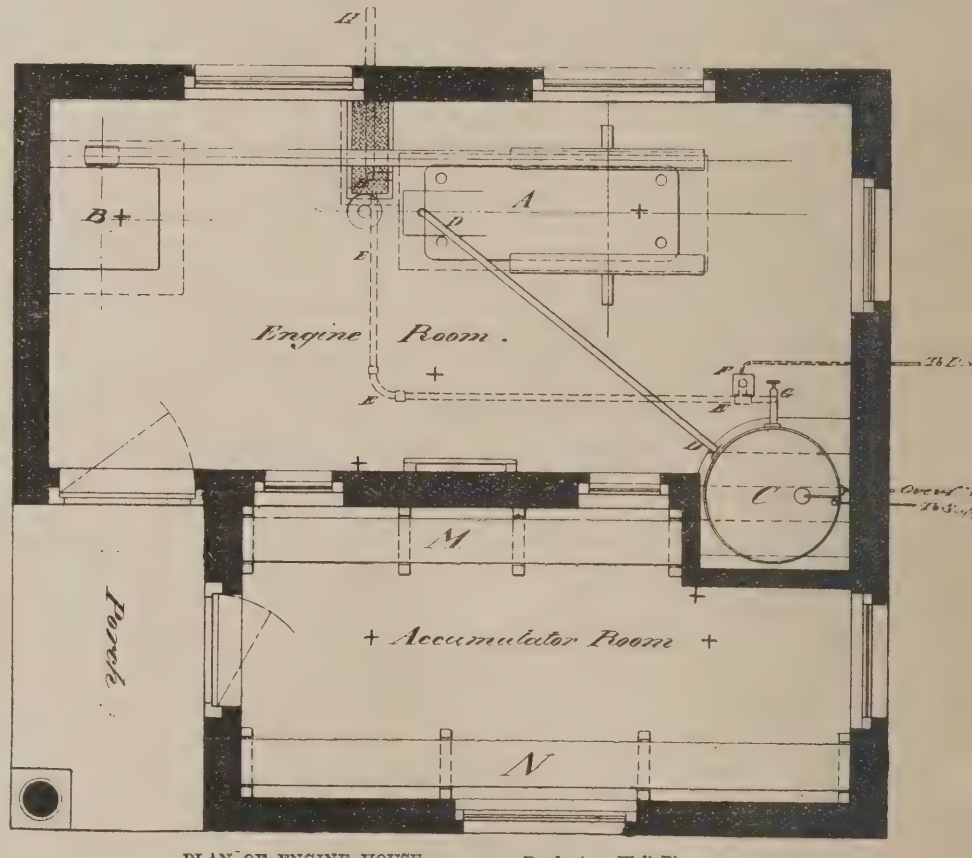
The mains to the house are of No. 19/16 armoured cable, which may be laid straight into the ground without piping or other protection.

It should be noted in connection with the switchboard that the circuit through which the current passes when the accumulators are being charged is termed the "charge" circuit, that which takes in the lamps the "discharge."

The switchboard is of enamelled slate. I have shown it in two pieces, encased in an oak or mahogany frame, which adds to the finish of the board and covers the battens to which the slates are screwed.

The shunt resistance and switch for regulating the pressure of the current from the dynamo are made both separately and combined; if not used in the latter form the switch is put on the switchboard, and the resistance somewhere near. I have shown the switch in this way at F.

The dynamo main fuses should be placed in circuit as near to the dynamo as possible, either on a board or on the casing conveying the leads to the switchboard.



The regulator, J, is for regulating the voltage of the battery, as the shunt resistance does that of the dynamo. The end thirteen or fourteen cells are connected to the regulator in such a way that either all or part of them may be cut in or out, as required.

The automatic battery switch, S, is a most useful device, which should never be omitted in an installation of this kind. It is inserted in the "charge" circuit, and if at any time the E.M.F. of the accumulators exceeds that of the dynamo, even if only by one or two volts, it immediately breaks the circuit, and causes the bell shown at O to ring until the charge switch is opened. The bell can be prevented from ringing by keeping the switch at L open.

Two ammeters, one on the "charge" and one on the "discharge" circuit, are used by some firms, but perhaps the majority use one ammeter and a two-way switch. I have, however, shown two here, at B and C. The voltmeter key is really a species of two-way switch, which enables the reading to be taken on the "charge" or "discharge" at will. The voltmeter is shown at A. The switch D is for controlling the "charge" circuit; E that controlling the "discharge." G is the main fuse protecting the "positive" end on the battery.

Cost.

The initial cost of an installation may vary between pretty wide limits. For this example I have not made economy my principal aim. There are many necessities generally supplied by the builder, and a certain amount of work must be done by him in addition to the actual building of the engine-house, which all adds to the real cost of the installation, but this is not, as a rule, in the electrician's estimate.

PLAN OF ENGINE HOUSE. + Pendant or Wall Plug.

The following figures may be taken approximately to represent the cost of the part of this installation treated in this article, exclusive of the builder's contract, the prices allowed being those generally prevalent amongst the best London electricians:—

	£	s.	d.
Engine	119	10	0
Additional flywheel	7	0	0
Dynamo	38	10	0
Bolts, &c.	2	2	0
Accumulators	103	15	0
Cable, &c., for battery connections	5	0	0
Switchboard	29	10	0
Shunt resistance	3	0	0
Belt	2	10	0
Piping for engine			
Labour on engine and piping			
" " dynamo	30	0	0
" " switchboard			
" " accumulators			
" " wiring for eight lights			
Main cables to house, and laying same	7	10	0
Five plain pendants, two wall plugs, and four switches	1	10	0
Eight lamps	0	17	0
Two portable hand lamps	1	7	0
Portable voltmeter and contact rod	2	2	0
Hydrometer	0	2	0
	£354	5	0

To the item of labour, &c., the travelling expenses and lodgings of men must be added as the travelling expenses, and the charges for the carriage of goods, depend entirely on the locality of the installation, these must be added to the above figures. The plans of the house for which this plant is designed, showing the system of wiring and the positions of the various fittings, will be given in the concluding article.

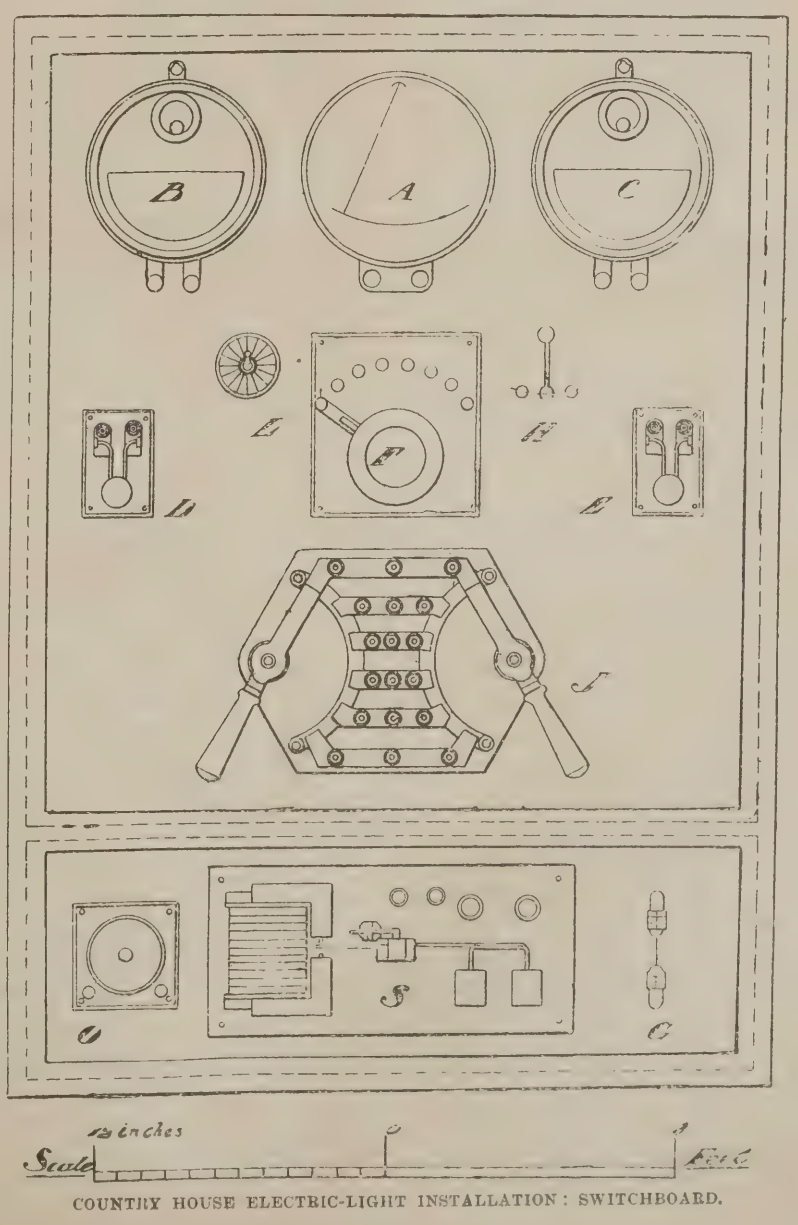
(To be concluded.)

Professional Practice.

Aberdeen. — Considerable alterations have been commenced in the building comprising 115 to 119 Union Street with the object of converting the numerous offices and shops which formerly occupied the building into an extensive emporium for Mr. R. K. Smith, hatter and clothier. The scheme of reconstruction, which is being carried out according to the plans of Mr. R. G. Wilson, shows that the ground floor in the Green will be converted into a packing-room, goods being received there. On the first floor a spacious saloon will be constructed. The main entrance in Union Street will be of an ornate character, the ornamental façade including also the floor above Union Street. While the main floor will be devoted entirely to sale-room purposes, the first storey above Union Street will constitute the tailoring department. The four floors will be communicated with by means of an electric elevator situated at the rear of the building. The upper floors are to be set apart for offices, &c.

Liverpool.—A new sanatorium for consumption is being erected at Delamere Forest as an accessory to the hospital in Mount Pleasant. The main block contains doctor's rooms, matron's rooms, and small sitting-rooms for special cases, with accommodation on the first floor for a limited number of patients. Directly behind this block comes the dining-hall, to which there will be no means of approach except through the open air; and behind that, again, the block containing the kitchen and servants' accommodation, similarly approached. The bulk of the patients are to be housed in small detached blocks containing four or six bedrooms apiece, with the requisite baths, &c. These small blocks will be dotted about the estate in such positions and numbers as may be felt to be

required. Attached to the main block, and to each of the smaller blocks, will be verandahs with a south or south-west aspect, so as to afford opportunity for rest and shelter in small companies, and each bedroom in the main block communicates with a balcony upon which the bed may be placed. Since it is a principle of the treatment to keep patients as far as possible in one temperature fireplaces in the rooms are not required. Everything is arranged for the free circulation of the fresh air outside. In order to avoid opportunities for the lodgment of dust mouldings and irregularities of surface have been carefully eliminated, and all corners and angles are rounded. It is proposed to utilise electricity very largely in the working of this sanatorium, to light, do what little heating may be required, and provide any necessary power by its means. A pure water supply can be got from various sources, including the Vyrnwy main of the Liverpool Corporation, which will pass within a mile of the site, on its way to Wallasey. The designs for the buildings have been prepared by Messrs. Willink and Thicknesse, of Liverpool. The contractors for the buildings are Messrs. J. Gerrard and Sons, Swinton, Manchester; and the clerk of works is Mr. James Hibbert.



Newcastle.—The foundation stone of the new Presbyterian church for Blackett Street was laid last week. Messrs. Badenoch and Bruce were selected architects for the new church in a limited competition in July, 1899. The hall is well forward and will probably be ready for occupation about Christmas. The church is planned with a wide nave, narrow aisles and transepts, and will have seating accommodation for about 620 on the ground floor, and about 180 in a gallery to be erected at the main entrance end. A spacious porch and vestibule will give access to the church and to ladies and gentlemen's cloak rooms opening to right and left. To the gallery fireproof staircases will ascend at each side. The means of exit will be ample, and are to include the main entrance porch, a porch in the side street, a porch to the hall and two other doors at the north end of the church. The hall entrance is from College Road. The accommodation is for about 500. The block of buildings immediately in front will have upon the ground floor a committee room and an infants' classroom. On the first floor there will be a session room and ladies' room with bay windows overlooking Barras Bridge. The caretaker's house will consist of the second floor above. At the rear of the hall on the ground floor there are to be a retiring room, a large kitchen, with boilers, a china closet, &c., for use at tea meetings. The place assigned to the minister's vestry is behind the church, with entry from a private door and corridor communicating with the church and hall. The building throughout is being walled in local stone with chiselled dressings, and is to be heated by low-pressure hot water, with pipes and radiators, the heating chamber being placed under the hall vestibule. The ventilation will be by fresh-air inlets, the vitiated air being drawn off from the roof and exhausted by a fan placed in the tower. The illumination will be by electricity, though a supplementary gas service will be furnished. The area of the site is about a quarter of an acre. Mr. G. H. Mauchlen is contractor for the building. The heating will be done by Dinning and Cooke, and the electric lighting by Messrs. Falconar, Cross and Co.

Stratford, E.—St. Matthew's Mission Church, in Vicarage Lane, was dedicated recently. The style adopted is the early period of Gothic. The main gable of the church is flanked on either side by bold pilasters, one terminated with a gabled canopy, the other being carried up as an open bell turret terminating in a spirelet carried by four dwarf stone columns with carved caps. The spirelet is covered with oak shingles, and finished with a wrought-iron weather-vane. A five-light centre traceried window forms a feature in the front gable. A narthex containing two main entrances relieves the front elevation. The chancel arch of Bath stone is carried on columns of the same material. The roof is of open timber hammer-beam construction, with boarded ceiling, and the timber is stained dark walnut. The vestry is arranged by the side of the chancel. Class-rooms, kitchen, and other conveniences are placed in a basement. The building has been erected from the designs, selected in competition, submitted by Messrs. George Baines, F.R.I.B.A., and Reginald Palmer Baines, architects, 5 Clement's Inn, Strand, W.C. The builders were Messrs. Battley, Son and Holness.

Woolwich.—The new Grand Theatre was opened last week by Sir Henry Irving. The theatre occupies a central position in the town, has a frontage of 80ft. and a depth of 160ft., and is one of the largest suburban theatres. It is built of red brick, with Bath stone pilasters and dressings, side turrets, and a central domed roof, having a handsome iron corona. In the front are four powerful arc lamps, and the interior is lighted with 1,500 electric lamps. The stage measures 43ft. by 80ft., and the height to the grid is 56ft. The auditorium has a width of 62ft. and a depth of 75ft., the entire seating accommodation being for 3,000 persons. It is built on the cantilever principle, with not a column or pillar anywhere in the place; and is claimed to be the widest theatre, if not the widest building, ever erected on that principle. The decoration of the auditorium is in the style of the First Empire. The exits are very numerous, being duplicated in every part of the house. The bars, lounges, and retiring rooms are all of a very commodious type. The architect is Mr. B. Crewe, and the contractors are Messrs. W. Johnson and Co.

ENGLISH MEDIÆVAL ARCHITECTURE.

AT Owens College, Manchester, last week Professor Simpson began a course of six lectures on English mediæval architecture. He said it would be a mistake to start straight away with Gothic work in England, because its development would be very difficult to understand without some slight knowledge of the different styles that preceded it. It must be remembered that a history of architecture was a history of evolution. Thus the Greeks learned from the Egyptians, Assyrians, and Persians; the Romans learned from the Greeks; the older Italian builders, whose style was commonly called Romanesque, learned from the Romans; and the Gothic men in turn learned from the Romanesque builders. It was not till the Renaissance in the fifteenth century that any change in this procedure took place. Then for the first time builders harked back to the style of a period many centuries before the age in which they lived. All building, the lecturer went on to say, could be divided under two main heads. There were only two methods of bridging over an opening—one was by a lintel or beam and the other was by an arch; and it was either of these two methods of construction brought to perfection that constituted a great style. So the two great styles of architecture were the Greek and the Gothic, because it was in these two styles that the two different methods of construction were brought to perfection. He thought the title of "great" could not be given to the Roman style. The Roman work was no doubt magnificent, but its magnificence was owing more to constructive skill than to architectural style, and its ornamentation did not, as in the case of Gothic work, arise out of the method of construction adopted. Professor Simpson proceeded to deal with the early Christian work in Italy, for it was from this work, he said, that Gothic architecture, though perhaps indirectly, sprang. The lecture was illustrated by lantern slides.

COUNTRY HOUSE ELECTRIC-LIGHT INSTALLATION: SWITCHBOARD.

New Patents.

These patents are open to opposition until November 26th.

1899. — Plastering. — 19,921. J. BASSETT, Sherbourne Street, Ladywood, Birmingham. The object of this invention is to avoid the necessity for lathing, and to hasten the work of plastering. Slabs (preferably 3ft. by 2ft. 3in.) are employed, consisting of a coarse adamant plaster with a strip metal skeleton moulded within. These slabs are fastened in place by nails, and the wall surface is then in a finished state, or in the condition known as "rendered, floated and set."

Water Taps.—19,955. M. J. ADAMS, Park Lane Sanitary Works, Leeds. A tap made according to this invention will deliver hot and cold water from a nozzle by simply screwing down one spindle. This opens its own valve, and presses on a lever which lifts and admits water through the other valve.

Sawing Machinery.—21,173. G. PICKLES and J. T. PICKLES, Royd Iron Works, Hebden Bridge, York. This invention consists in applying to the cranks of wood-cutting and sawing machines balance weights (attached to, or made integral with, the cranks), for the purpose of obtaining more regularity and greater smoothness in action.

Lift Wells.—22,141. F. TOYE, 3 Maryland Road, Chitt's Hill, Wood Green, London, N. The wells in which lifts work naturally constitute a source of danger in case of fire by reason of their acting as chimneys. To obviate this, the invention under notice arranges at each floor-level a hinged flap which can be shut down when needed. All the flaps can be operated simultaneously.

Cutters for Wood-working Machines.—22,893. R. PERRIN, 26 Landseer Road, Breck Road, Everton, Liverpool. The cylindrical block in which the cutters are mounted forms a bearing against which the timber rests when being cut or moulded, even though there be a mortise or hole in the guiding surface of the wood. In ordinary apparatus, when the mortice or hole was arrived at, there would be no support and the cutters would cut into the wood and spoil its evenness of surface.

Sanitary Pipe Machines.—24,408. J. STALEY, Albert Village, Church Gresley, Derby, and J. PARKER, Moira, Leicester. By a device of slides passing through suitable stuffing-boxes above the die, operated by means for obstructing the passage of the clay, it is possible to form in the machine a pipe with a sharp bend, or with double bends.

Wall Plugs.—24,883. R. HADDAN, 18 Buckingham Street, Strand, London (communicated by I. Friedinger, Upper Austria). The plug consists of a wooden cylindrical body with a wedge-shaped hole in it at one end. It has a ring at the outer end. The plug is placed in the wall and a wooden wedge is then driven in, expanding the plug and making it grip the sides of the hole—independently of the nails, hook, or screw which it is to receive.

The following specifications were published on Saturday last, and are open to opposition until December 3rd. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—14,350, LOWE, manufacture of bricks. 19,193, DUNCAN, NEW SUNLIGHT INCANDESCENT CO., LTD., & BARNETT, apparatus for lighting gas. 19,557, THWAITE AND ALLEN, acetylene gas generators. 20,489, VON BIELINSKI, bricks and paving blocks. 21,427, HOLLOWAY AND B. DELLAGONA AND CO., LTD., apparatus for spraying colour, slip, glaze, and enamel. 21,530, BARR, apparatus capable of being used as a ladder, an extensible ladder, a pair of steps, or a trestle. 21,726, MARSHALL, bricks for building flat arches. 22,895, PODMORE, screw fasteners for doors and windows. 23,064, JOSEPH PLACE AND SONS, LTD., AND PLACE, gullies and traps for them. 23,076, HOUGH, arrangements of fire bars for boiler and other furnaces, domestic fire-grates, &c. 23,451, HARLEY, window sashes. 23,463, GIBSON, tile-like decoration suitable for fireplaces. 23,510, EDWARD WOOD AND CO., LTD., AND BUTLER, staircases constructed wholly or partly of metal. 23,576, BROPHY, radiators for warming buildings. 23,758, PETTERSON, method of producing acetylene or similar gas. 23,892, BURGESS, bucket water lifts. 24,092, WATHIER, tube cutters. 24,247, HADFIELD AND JACK, tramway points.

1900.—848, LINKLETER, cowls for chimney tops. 5,895, GOLBY (*Groegor*), means for fixing ornamental plates on walls. 6,608, BOULT (*Sauvan*), gas or vapour burners. 6,993, FELL, disinfecting appliances for water closets. 11,945, VOGELAAR, nails and means for driving them. 12,335, SLOCUM, manufacture of gas. 12,501, PAGE, devices for supporting persons in windows while engaged in painting or similar occupations. 13,703, CHANTRY AND MILBANK, syphon water-waste preventing apparatus. 14,486, MÜLLER AND THOMAS, steam radiator for buildings. 14,672, DEAN, casement fastener. 14,944, CLOSMANN, filters. 14,957, SUGG, incandescent gas lighting. 15,322, LAKE (*Mönnig*), adjustable skylights.

NEW LAMBETH BRIDGE.

IN a letter to the "Daily Chronicle" Professor G. Baldwin Brown, of Edinburgh, decries the proposal to apply to some leading authority on Gothic architecture to clothe the piers of the new bridge at Lambeth with appropriate detail. He says: "If the bridge is to be a good one it will harmonise well enough with its surroundings; and if it is a bad bridge no amount of Gothic detail licked over ugly piers will be of any real artistic value. The bridge will presumably be of steel. It is perfectly possible for a structure in this material to be artistic, both in general form and also to a great extent in detail, but this can only be the case if the material is frankly used, and does not pretend to be something else, or hide itself away behind screens or shams. . . . As to stone piers, they need not trouble about special historic styles in details—least of all about Gothic details, which might harmonise with a building a quarter of a mile away, but would be woefully incongruous with the actual structure to which they belong. If the piers are made to do their work, and are seen to do their work, a very little artistic modification of their forms, and the emphasising of these by some well-considered tectonic features, would be all that is required. The idea of the co-operation in undertakings of the kind of the engineer and the architect is at best a lame sort of compromise from which there is little to hope. The art of the structure should be a development from within, and this is in the hands of the man who controls the material and the manner of its use. . . ."

Views and Reviews.

Defects in Plumbing and Drainage Work.

The new and enlarged edition of this useful little book, by the well-known Medical Officer of Health for Cheshire, is a meritorious work. It is written in such an easy and simple manner that laymen should have no difficulty in understanding whether their sanitary fixtures are or are not in a safe and proper condition. Apart from this, however, the book will afford technical readers, and especially students, much useful information about faulty work, the author having written up and illustrated a large number of faulty pieces of work which came under his jurisdiction and notice. A study of these pages will perhaps save some of the older workmen from perpetuating the old time-honoured methods of work which, in the light of our increased sanitary knowledge, are dangerous and obsolete. Altogether a book to be bought and studied.

"Defects in Plumbing and Drainage Work." Described by Francis Vacher. New and enlarged edition. With 120 illustrations. 1s. nett. John Heywood, Manchester.

Law Cases.

Dispute about Skylights.—At the Clerkenwell County Court last week Messrs. R. Bristow and Sons, builders and contractors, of 35 Red Lion Street, W.C., brought an action against Henry Holmes, of 3 Leicester Road, Moreland Road, Croydon. In this action the plaintiffs claimed £11 5s. 1d. for making two skylights, reglazing a skylight, and other work at the defendants' premises, Goswell Road. Counsel explained that according to the original specification the plaintiffs had to make water-tight certain skylights on the premises in question; but in the course of stripping they were found to be absolutely useless, and it was impossible to make them water-tight. This was pointed out to the manager of the defendant, and new skylights were put up. An objection was not made until months afterwards, when it was complained that the skylights were not water-tight, and that they had to be put right. The manager to the plaintiff firm gave evidence in support of this statement; but it was contended in defence that skylights had been broken by the plaintiffs' men. The Judge said the work had been carried out, and how the defendant could defend the action he did not know. He gave judgment for £10 12s. 10d.

A Mortar Mill and an Engine.—At the Bristol County Court last week, before his Honour Judge Austin, Messrs. W. H. Coward and Co., engineers, of Bath, sued Messrs. H. A. Forse and Sons, builders, of Bristol, for £90 in respect of a second-hand mortar mill and engine supplied by them to the defendants. The mill was sold as having a 7-ft. pan and was priced at £40; the engine was of 8 horse-power, and was sold at £50—about a quarter of its value when new. The defendants found that the mill had only a 6-ft. pan, and the plaintiffs offered to take it back; defendants replied that plaintiffs would have to pay carriage; the engine they declared to be unfit for use. In giving judgment his Honour said that the delay of the defendants in repudiating the machine as not according to contract was unreasonable, and both in this particular and in the fact that the defendants had the mill repaired, he must hold, confronted as he was with the Sale of Goods Act, 1893, that the defendants must stand by the result. As regarded the engine, he had felt more doubt, but must come to the conclusion the defendants must take that as well. It was unfortunate there was not some legislative interference with dealings in machines of this sort. Probably there were few things more dangerous than an elderly portable engine, pretty well worn out, and patched up; a thing which cost £200 to buy new, but which was purchased for £50. He gave judgment for the plaintiffs for £90, but without costs.

Fire-resisting Construction between Trade and Private Premises.—The New Westminster Brewery Company appealed to Mr. Kennedy at Southwark Police Court on Wednesday last against a notice of objection, served by the district surveyor on behalf of the London County Council, to the rebuilding of the "Horse Shoe" beer and wine-house, Old Kent Road. Mr. Gates (for the appellants) said the case raised a very important point under the 74th section of the Metropolitan Building Act. The plans for the rebuilding of this house had been approved by the licensing justices, but the County Council raised an objection that the living rooms on the upper floors ought to be protected and separated from the lower portion of the premises by the use of fire-resisting materials. A Divisional Court had already decided that such a separation or precaution was not required in a fully-licensed house, and he could not understand how a beer-house was to be made the subject of a different ruling. Mr. Avory (for the County Council) replied that the Council were not satisfied with the decision of the Divisional Court in the case referred to, and desired to have it reviewed. They held that the provisions of the Act, requiring the use of fire-resisting materials between the part of the building which was used for trade purposes and the part which was used for private occupation, did apply to publichouses and beer and

wine-houses, and they hoped they would not again be checkmated in getting a decision on that very important point from the very highest Court. For the present, however, they must accept the decision of Justices Day and Lawrence, that as liquors might be sold in the bedrooms of an inn the trading and the private portions of the premises could not be distinguished. Beer-houses, however, were simply shops for the sale of beer, and the upper part was entirely private. Mr. Kennedy reserved his decision.

Keystones.

A new Church at Swinton, near Rotherham, is being erected at a cost of £2,400.

A Parish Hall for St. James's Parish, Dover, is to be erected between St. James's Street and Russel Place.

Lintale Church has just had a new stained-glass window added, the work of Messrs. Shrigley and Hunt.

A Fever Hospital for Perth is proposed to be erected upon a site at Hillend, subject to the Local Government Board's approval.

Competition for New Asylum at Cardiff.—This competition will not be decided until the end of this year or the beginning of next.

New Cottage Homes for the Poor at Dewsbury have been opened in Dewsbury Park at a cost of £8,000. Mr. F. W. Ridgway is the architect.

Mr. Mark J. Lansdell, F.R.I.B.A., of 38 Bow Lane, E.C., has had his plan for a new cemetery lodge accepted by the Bexhill Urban District Council.

Lupton Church, Kirkby Lonsdale, has, under the superintendence of Mr. Curwen, architect, been redecorated by Messrs. Croft and Baines, of Kirkby Lonsdale.

The Site for the Gladstone Statue at Edinburgh is to be in the garden facing Coates Crescent, and the execution of it is to be entrusted to Mr. Pittendrigh MacGillivray.

At Flookburgh New Church an organ has been built by Messrs. Brindley and Foster, of Sheffield. A peal of four bells from Taylor's, Loughborough, is also being placed in position. The altar frontals and hangings have also arrived: they have been designed by Watts, of London.

Messrs. Yamanaka & Co., of Osaka, Japan, have opened a branch establishment at 68 New Bond Street, London, for the sale of Japanese art work, both ancient and modern. Consignments of artistic work will be received direct from Japan from time to time, and collectors interested in any special classes of art-work will be regularly advised of shipments, provided they notify to the firm particulars of their requirements.

The New Union Church at Lynn is being erected in Wisbech Road. The church will be in the Early English Gothic style, in red brick with white Costessey-ware dressings. It will be cruciform with nave aisles, transepts, and an organ and choir gallery behind the pulpit, the dimensions being 60ft. by 40ft. with accommodation for 320 sittings. The windows will be mainly lancets, and the nave will be divided from the aisles by arches and pillars. The main entrance will be at the end farthest from the school. The architect is Mr. J. L. Carnell, and the builder Mr. W. F. Smith.

Presentation to a Stockport Architect.—At a meeting of the Stockport Lads' Club a presentation of a silver spirit flask and a silver cigarette case was made to Mr. A. G. Wilkinson, architect, of St. Petersgate, who has taken a great interest in the Lads' Club since its inception, and has on many occasions given the committee the benefit of his professional experience in structural alterations. Recently a new roof has been added to the gymnasium and other important alterations done to the building under the superintendence of Mr. Wilkinson, and so grateful were the committee for the help thus given that they decided to mark their appreciation with this gift.

A Bust of Chaucer is to be placed in the City of London Guildhall.

A Stained-glass Window is to be placed in Christ Church, Wycombe.

The Parish Church of Ripley, Surrey, has had a stained-glass window added.

The Parish Church of Chalfont, St. Giles, has just had a new east window and reredos added.

A Free Library for Bow is being erected in Roman Road. Mr. S. B. Russell is the architect.

Mr. Joseph Goddard, a well-known Leicester architect, died on October 10th, in his sixty-first year.

The Duke of York Inn, Great Yarmouth, is being rebuilt from plans by Messrs. Harrington and Ley, of 65 Bishopsgate Street Without, E.C.

A New Public Library and Reading Room at Hawick is to be erected at a cost of £10,000, which money has been given by Mr. Andrew Carnegie.

Some good Drawings of Architecture, by Mr. Fulleylove, are to be seen at the exhibition, now open, of the Royal Institute of Water Colour Painters.

A Free Library for Limehouse is being erected at the corner of Norway Road, fronting Commercial Road East, at a cost of about £8,000. Mr. W. Clarkson is the architect.

The Passmore Edwards' Museum at Stratford, in Romford Road, was opened last week. It has cost about £4,000. The architects are Messrs. J. S. Gibson and S. B. Russell.

Albrecht Devriendt, Director of the Belgian Royal Academy of Fine Arts, has just died. He was born at Ghent in 1843, and was famed for his decorative pictures in the City Hall at Bruges.

St. Sidwell's Church, Exeter.—The vestry of this church have approved the plans of Mr. E. H. Harbottle, the cathedral architect, for the renovation of the western tower. Application is to be made to the Chancellor for a faculty.

The New Church of St. Luke at Grayshott, Hindhead, was consecrated last week. It has cost about £8,000, seats 300 persons, and is in the Early English style. The architects are Messrs. I'Anson and Son, of Laurence Pountney Hill, E.C.

Housing Question at Woolwich.—In consequence of the unprecedented activity in the Royal Arsenal in connection with the South African and other wars, the Royal Arsenal Co-operative Society are about to erect 4,000 additional dwellings for artisans, on their estate at Bostal.

The Birkbeck Institute has, during the summer vacation, had several additions and improvements made. The rooms have been fitted with the electric light, enlarged and refurnished, while a new reading-room, new magazine-room, and a social room have been provided for the use of the students. A new metallurgical laboratory has also been founded and fitted with every modern appliance.

The Architectural Association's Conversazione was held last Friday evening at the Holborn Restaurant. Mr. W. Howard Seth-Smith, the president, and Mrs. Seth-Smith received the members and guests, who numbered about 500. The prize drawings by students of the association and the work done in the studios and school of design were exhibited. During the evening Mr. Richard Kerr and Miss Kerr gave demonstrations in connection with wireless telegraphy and the X-rays. Instrumental music was provided by the Bijou Orchestra.

Annuities from the Royal Academy.—The president and council of the Royal Academy of Arts will proceed on November 6th to elect one Cousins annuitant and one or more Turner annuitants. The Cousins annuity, which is of the value of not more than £80, is for deserving artists, painters in oil and water-colours, sculptors, architects or engravers in need of aid through unavoidable failure of professional employment or other causes. The Turner annuity, of which the value is £50, is confined to artists of repute in need of aid from the same reasons.

Seven Tenements in Edinburgh are to be erected in Comely Bank Street.

A Monument to Chopin has been erected in the Luxembourg Gardens, Paris.

A Flagstaff at the Royal Courts of Justice has been erected on the Clock tower, and is most displeasing in effect.

The new Artizans' Dwellings at Hull, illustrated in our issue for October 3rd, are now being erected, the foundation-stone having been laid last week.

For Emitting Black Smoke from their chimney shaft the New London Brewery Company, Limited, of Durham Street, Vauxhall, has been fined £10.

A new Wing at the Victoria Infirmary, Glasgow, has been opened to provide additional accommodation in the Nurses' Home for twenty-eight beds.

A Pulpit in Tuxford Parish Church has just been erected by Messrs. Harry Hems and Sons, of Exeter. It is in marble and alabaster, and is in the Perpendicular Gothic style.

For the Erection of a new Workhouse at Wolverhampton £100,000 at 3½ per cent. has been borrowed by the town guardians. The Public Works Loan Commissioners are to advance this sum.

A new Mission Church at South Lynn, dedicated to St. Michael and All Saints, is being erected at a cost of £2,000. A school is also being erected at a cost of £1,500. Mr. L. F. Eagleton is the architect and Mr. R. Dye the contractor.

A Pulpit in Stratford-on-Avon Church has been erected, at a cost of £1,000, by Sir Theodore Martin as a memorial to his wife, Helen Faucit. The pulpit, of dark green marble and alabaster, is Perpendicular Fourteenth Century in style, and was designed by Mr. G. F. Bodley, A.R.A.

A new Mission Church at Roundhay, Leeds, is being erected on a site in Lidgett Park. A vicarage and parochial hall is also to be built. The new building, for which Mr. Carby Hall is the architect, is designed to accommodate 250 persons, and will be substantially built of stone. It will cost about £1,500.

Proposed Public Library and Museum at Chatham.—A Local Government Board enquiry was held recently with reference to the application of the Town Council for sanction to the appropriation of a site at the rear of the Technical Institute, New Road, for the erection of a public library and museum, and to borrow the sum of £2,500 for the erection of the same. Mr. G. E. Bond has prepared the plans.

A new Baptist Congregational Church at Woking is to be erected, with a lecture hall, at a cost of about £6,000. The hall is to be built first, with the necessary adjuncts of a kitchen, vestries, classrooms, church parlour and kitchen, at a cost of about £2,500. The hall is to seat 250 persons, and the church 450, with provision for enlarging the latter. The architect is Mr. W. Howard Seth-Smith, F.R.I.B.A., President A.A.

The Holborn-to-Strand Street.—The County Council authorised its Improvements Committee to spend fifty guineas in obtaining expert advice upon the designs for the new street. The committee now report that Mr. R. Norman Shaw, R.A., has readily accepted their invitation to advise upon the designs, in association with the Council's architect, but has expressed his desire not to accept any fee, as he states that he is anxious to place his services "at the disposal of a body engaged in the congenial occupation of beautifying the architecture of the city in which one dwells." A scheme has been drawn up for rehousing the 3,700 persons whom the scheme will displace. On the Duke Street site and Marquis Court site accommodation will be provided for 250 (in addition to 750 displaced by the Clare Market clearance); in a lodging-house at the corner of Kemble Street and Drury Lane, 799; on Reid's Brewery site, 1,681; on the Herbrand Street site, 680; and on the Millbank site, 290. We are relieved to hear that the new homes are to be ready for occupation before persons are turned out of their present quarters.

A new Organ in Alyth Parish Church has been erected by Messrs. E. F. Walcker and Co., Ludwigsburg, to the specification of Mr. David Stephen, Dundee. The case was designed by Messrs. Johnston and Baxter, architects, Dundee.

New Technical Institute for Burnley.—The Burnley Town Council have accepted the plans of Mr. Thomas Bell, of Burnley, for the proposed new technical institute to be erected in Piccadilly Gardens, the cost of which will be about £40,000. There were three sets of plans sent in, this being the second competition. Mr. W. S. Cross, of Manchester and London, acted as assessor on the plans.

Thwing Parish Church, East Yorkshire, has been reopened after restoration at a cost of about £2,100. As a memorial of Archbishop Lamplugh a new porch has been erected by Mr. C. E. Lamplugh. The ancient features of the church have been preserved. The old font, which was found in a garden in a neighbouring parish, has been transferred to its original place.

A new Mission Room at the New World, Doddington, has been erected. The building is in the Gothic style, and is capable of seating comfortably about 90 persons. It has been built from plans prepared by Mr. Robert Wade, of Doddington, the contractor being Mr. T. W. Dack, of the same place. The site adjoins the main road from Doddington to Benwick. The estimated cost of the work is £160.

The Late Mr. Hanstock of Batley.—We regret to announce the death of Mr. Walter Hanstock, architect and surveyor, of Branch Avenue, Batley, which occurred on October 13th, at Harrogate, where deceased had been staying for the last nine weeks. Among his designs are about 30 chapels up and down the country, the Batley hospital, mission hall, public baths, the Leeds baths (five in number), Leeds abattoir, most of the Board schools in Batley, several mills, an hotel at Ashover, in Derbyshire, besides many private villas and the plans for the restoration of several churches. Quite recently designs prepared by the deceased's firm, Messrs. W. Hanstock and Son (Mr. Arthur Hanstock succeeds to the business), for the Belfast Church Institute and for the proposed new covered market at Leeds have been awarded the second prize in competition.

The Midland Dairy Institute, Leicester, has opened a new block of buildings, which will afford facilities for the study of science with a view to its practical application to agricultural and dairying on the farm and in the dairy of the institute. The new buildings consist of a chemical laboratory, where the students will be taught how to analyse feeding stuffs, their application to different soils, and their effect on certain crops. A laboratory has also been provided for the testing of milk, and the isolation and control of germs which have been proved enemies to the dairy farmer. A hostel has been erected in which will be housed the the male students, and a manager's house has been built. The cost of these extensions to the governing body is about £1,200, exclusive of the manager's house, which has been erected by Lord Belper at a cost of £600, and is rented to the institution.

Proposed Municipal Buildings at Leigh.—The Town Council of Leigh have approved the recommendations of the Surplus Lands Committee—that the architect be instructed to prepare plans and sections of the proposed new municipal buildings to be erected in Market Street for the Local Government Board, in connection with the application by the committee to the Board for sanction to borrow the money necessary; and that the committee visit a number of town halls with the view of ascertaining the sizes and disposition of the various rooms therein; and that the mayor, chairman, town clerk and architect draw up a list of the halls visited. The recommendation of the Technical Instruction Committee that Mr. J. H. Stephen be requested to prepare quantities and get tenders for the proposed extension of the technical school and library, including £968 for an additional reading-room and £2,100 for class-rooms and physical laboratory, was approved.

The Edinburgh City Chambers are to be extended north-westerly at a cost of about £16,000.

The Yorkshire Home for Chronic and Incurable Cases is erecting a new building at Harrowgate at a cost of about £15,000.

A Mission Church at Churchill, Bristol, has been built by Field-Marshal Sir Lintorn Simmons as a thankoffering. It will accommodate 120 persons, and will be an adjunct to the parish church.

The Sandal Board Schools, Wakefield, are being warmed and ventilated by means of Shorland's patent Manchester grates, patent exhaust roof ventilators and special inlet panels, supplied by Messrs. E. H. Shorland and Brother, of Manchester.

New Church School at Oxford.—The Sisters of the Convent of the Holy and Undivided Trinity, Woodstock Road, Oxford, have long carried on a middle-class day school for girls. In order to meet an increasing demand for a higher-grade day school they have just opened a house at Bevington Road to be known as St. Faith's School.

A New Workhouse at Chandler's Ford, Hursley, has been opened. The new building has been built of bricks made in the locality, the builders being Messrs. Musselwhite and Son, of Basingstoke, and the architects Messrs. Cancellor and Hill, of Winchester. The cost of the new building is about £9,000; the land has cost another £1,000; and drainage, furnishing, and other matters will bring the total up to over £12,000. The building stands on high ground, approached from the Hursley Road.

New Companies.

Steel and Iron Improvement Company, Limited.

This company was registered on October 5th with a capital of £1,000 in 1s. shares to acquire any inventions by J. Mackintire or others, relating to the manufacture and production of steel and iron, and to carry on the business of ironmasters, iron and steel makers, engineers, &c.

An Architectural Causerie.

The Relation of Bunting to Architecture.

There are very few subjects indeed, in any way related to architecture, which Ruskin has not dealt with in some portion of his many works. And one of these few subjects is the proper significance of bunting as an attribute to architecture. At first thought it may be a trivial matter, but recent national events have given us extraordinary evidence of the striking effects which bunting can produce in conjunction with the simplest buildings. The public spirit which has prompted these lavish displays of colour is not, it must be confessed, in every case very happy in its resultant schemes, while some of the "flags" that have done duty cannot be called bunting in any sense of the word. But there has been enough demonstration to show that a striking national character can be imparted to buildings by a judicious and tasteful employment of bunting. It is very remarkable to think of the entire absence of colour from most of our important buildings of the past—massive and stately piles of grey and worn stone. How pleasing the addition of colour becomes we see at once when there is any form of vegetation applied to the walls; in the most beautiful instances, masses of red, brown, and golden creepers, and in more sober cases, plain dark and light green patches. But it is hardly satisfactory to see the form of a cornice completely enveloped by leaves, and Ruskin's principles would lead one to class vegetation as a harmful and "illegitimate" attribute to architecture, seeing that its presence tends to decay, and its culminating influence is reached in the scope it has in our ruined abbeys and monasteries.

If, however, there is no such debasing influence on the walls themselves all vestiges of colour in the building itself are gone, and it really seems desirable for the eye to have some relief from the mass of neutral tint. And the simplest way of achieving this—of giving the building at once a stately character of its own and a totally different aspect—is to erect a mast on the roof of the main wing and run up an English Standard; when this is floating over the pile the necessary "piquancy" is added that prevents the eye from being morbid in contemplation of the house without such attribute. As instance of this effect attention might be drawn to St. Martin's Church in Trafalgar Square; while fully appreciating the noble aspect of the church it is eminently heightened when the flag is flying from the "spire"; and how stately such piles as Chatsworth and Stoneleigh Abbey look when our flag is flying over them! I have not forgotten window boxes and the colours they can add to an elevation; and in country houses where flowers are plentiful and easily grown they give an air of freshness to the house which bunting does not. But the real love of flowers leads one to the garden and glass-house, and it would seem to be more satisfactory to try to do without bringing the garden into the house. The curious fact that some fronts present a more cheerful appearance when the house is empty, on account of the drawn blinds adding colour to the scene, suggests that the curtains and window draperies should have some part in the colour effect of the exterior.

We do not want to see a flag flying from each window, nor any lavish display in bunting; but after natural stones it would seem to be the only other way of adding touches of colour without any such expensive and apt to be gaudy schemes as mosaic work or distempering; and it is only the finishing touch that is required, the culminating point to which the eye directs itself; and this point is the flag. A large part of the grand effect of the interior of Henry the Seventh's Chapel at Westminster is due to the presence of those tattered shreds over the stalls—still showing gold and vermillion—and the addition of linen of any sort is far better than a pedantic imitation of it in the stone. M** J.

London's Lost Opportunities

Washington has been described as "the city of magnificent distances"; London may be called "the city of lost opportunities." Many circumstances have combined to make it the gigantic place it is; its growth was foreseen, and the opportunity was presented when railways were first introduced of improving its great thoroughfares and laying

out new ones upon a systematic plan, of planting trees in them, and of laying out squares and circuses at their intersections. Something has been done no doubt since then, but, on the whole, the modern growth of London has been coincident with a separation of use and beauty. One of the greatest opportunities for dignifying and beautifying the town was lost when Victoria Street, Westminster, was built. Here was a great terminus in the heart of a residential district; within a mile stood the Abbey and the Houses of Parliament; to connect the two neighbourhoods by a great street was not a task presenting insuperable difficulties. The road was made, but the result is a failure. Incredible as it seems, the street is not straight; but even the turn might have been utilised to make the eastern section debouch upon the Abbey in such a way that it should appear at the end of a vista. Nothing of the sort was done; the street, moreover, was not designed with sufficient width; it is consequently very gloomy. Its City namesake, Queen Victoria Street, is much better in this respect, but again a great opportunity was lost in not bringing it out directly upon the Royal Exchange, whose fine portico would have grandly closed the vista. The removal of one half of the circus at Piccadilly should have been the occasion for a better arrangement than what we see; it is impossible to imagine anything more ungraceful, to say nothing of the neglected and usually waterless fountain. It is pleasanter to turn to the future. What are its prospects? Two great schemes are sanctioned, and will soon be commenced. One is the opening-up of a wide road and embankment beyond the Houses of Parliament; the other is the great street from the Strand to Holborn. What opportunities we have here for adding to the convenience and beauty of London; but will these also be lost? The former can only fail by hopeless mismanagement, but the latter scheme is beset by dangers, artistic and municipal. Here again architectural success depends greatly upon the treatment of the two ends; the crescent rising from the Strand especially. There is hope, however, here and for once, that genuine architectural effect is being considered by the powers that be.

It is considered by some critics that an opportunity will be lost by not utilising Gibbs' beautiful church of St. Mary-le-Strand to close the vista, though in fairness it should be said that the side view of it thus presented would not be as effective as that now seen when approaching it from Charing Cross. If the criticisms and suggestions of artists and professional men were supported in all cases of this kind, as they would be in Brussels or Paris, by a public keenly interested in the appearance of their city, we should not see so many lost opportunities; but Londoners differ from the people of other capitals in never taking any serious interest in an architectural question until it has been settled. Then they grumble. J. C. P.

Westbury-on-Trym Church.

REFERRING to the drawing by Mr. Lee Clarke on the previous page, Westbury-on-Trym Church is situated in a charming little village that lies in a valley about two miles distant from Bristol. The church is for the greater part of a comparatively late period, though some Early English work may be found in the windows of the south aisle. The view shown is taken from the churchyard.

On Reflection.

Holborn-Strand Designs.

THERE are designs now on exhibition at the gallery of the Royal Society of Painters in Water Colours which merit the closest attention and consideration, and afford suggestions for an excellent architectural composition. We publish a critique of these designs on another page, but it is now desired to make a few general remarks about them. It has hitherto been a matter of much speculation as to exactly what arrangement would be adopted in the disposition of the buildings, but it is now seen that the curve at the end of the straight portion of the new thoroughfare (see our issue for February 21st last) will have at its western end the "Morning Post" office, and at the other end Carr's Restaurant—with commercial buildings along the frontage—while the block between the curve and the Strand will probably consist of a central hall for the County Council, with the Gaiety Theatre on its western side and another building (an opera house is suggested) on its eastern side; at each side of the central hall there is a passage-way with a flight of steps at the end leading into the curved street. Such is the general disposition of the buildings. Many of the designs show archways over the ends of the several streets, an arrangement which produces an exceedingly fine effect. In some cases the main entrance to the central hall is provided from the Strand, preserving an unbroken line on the south side of the curve, and in others the reverse has been done. But, taken on the whole, it may be considered that the Council has the opportunity of effecting a great architectural improvement. The eight competing architects are Messrs. Reginald Blomfield, William Flockhart, Ernest George, Henry T. Hare, Mervyn Macartney, E. W. Mountford, Ernest Runtz and Leonard Stokes; but the designs are only numbered, and the names of their various authors will not be announced till after the close of the exhibition—on Saturday next.

The Steps of St. Martin's.

IT is only a short time since a protest was being made against the proposal to build over the western forecourt of St. Dunstan's Church in Fleet Street; but that protest was ignored, and, as shown in the photograph which we published in our issue for October 3rd, the extensions are now in progress, and we shall soon be able to see how successful the scheme has been in spoiling the lines of the tower. Now we have fears about Gibbs' beautiful old church at one corner of Trafalgar Square. It is pretty generally known that the Improvements Committee of the London County Council proposes to take away some of the steps of St. Martin's in order that the footway may be widened to about 9ft. On the south side of the church at the western end there is first of all a flight of six steps, then a landing about 10ft. wide, and then some more steps extending to the portico. The lower flight of steps tapers away to the slope of the ground, and finishes level with the pavement on the north side of the building. The Improvements Committee wishes to take away this lower flight of steps and the landing, and to form one continuous flight to the portico. It is true that St. Martin's first had a continuous flight of eight steps, but there was then no Duncannon Street, and that makes all the difference. As Mr. Thackeray Turner, the secretary of the Society for the Protection of Ancient Buildings, very truly points out, one flight of, say, twenty steps is not as dignified as two flights of ten steps each, separated by a landing, nor is it as safe. St. Paul's Cathedral would, indeed, lose in dignity if there were no landings in the steps leading to its western front. Moreover, the steps of St. Martin's carry on the level of the churchyard (which is shoulder-high in Duncannon Street), and so greatly improve the setting of the building. The proposal is not a mere passing fancy, but has been developed to such an extent that plans for reconstruction have been prepared, and Mr. Shaw Lefevre is therefore to be congratulated for having carried an amendment at last week's meeting of the Council to the effect that expert architectural opinion shall first be taken. But we are not yet without fear, for the "improvement" spirit is fiery nowadays. In this particular instance, however, there is little need for improvement. It will be noted that the pavement only is proposed to be widened, but there is no pressing need for this; while, if the carriage-way is deemed to be too narrow, the first thing is to prevent omnibuses stopping outside the church. When these have been made to stop in the lay-by on the north side of the building, it will be found that there is sufficient width of road; and even if there were not, it would be better to take a strip off the forecourt of the National Gallery than to remove the steps and landing which are so important to the architectural setting of St. Martin's Church.

Liverpool Cathedral Scheme.

LIVERPOOL has a cathedral scheme which has been mooted from time to time, and at the present moment it is again before the public, Archdeacon Madden having raised the ghost this time. It need hardly be said that the proposal finds strong advocates and bitter opponents, the former urging that the threshold of the twentieth century is an opportune time for erecting a great cathedral, the latter being equally convinced that this is not the case. Besides the main question, there are a number of side issues which are the subject of much discussion. Of these the most important is that relating to the site. Some (including the Archdeacon) declare that the enclosure of St. Peter's Church will form the best site; others are for Abercromby Square; others, again, for Monument Place, George's Dock site, and so on. The first-named is perhaps the site mostly favoured, but it is insufficient (being only 340ft. by 200ft.) for what is proposed to be a large cathedral. We have dozens of instances of the effectiveness of a building being lessened because of the limitation of the site—the London Law Courts, for example—and it would be better for the Liverpool authorities to wait till they had sufficient money at their disposal to obtain an ample site for their building. Then there is the style of architecture to be adopted—one advocating a Romanesque style of building with a Basilica ground plan, and another urging the adoption of Gothic. This we will leave alone for the present. As to cost, the idea of building a fine cathedral for £100,000 is surely absurd: it could never be done; and if there is not sufficient money forthcoming, it will be better to leave the project alone until there is. The cathedral is not a necessity, and it would be foolish to erect a building which showed in every part a lack of funds, resulting in a mimicry of what it might have been.

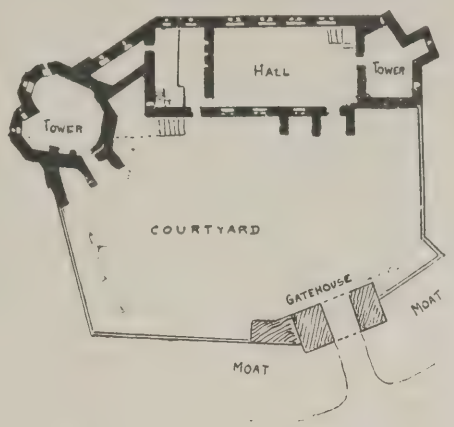
STOKESAY CASTLE.

BY F. H. CHEETHAM.

STOKESAY is pretty well known on paper by those who have given any time to the study of Domestic Gothic Architecture in England. It may be questioned, however, whether one in a hundred who know it from the pages of Mr. Hudson Turner has ever taken the trouble, or has had the opportunity, to make acquaintance with the building at first hand.

I can say nothing new about Stokesay from an architectural standpoint, for few of us have the opportunity to make that "much more careful examination" of the parts of this, or indeed any other, building that Mr. Turner recommended. I merely put down these few notes about this beautiful old Shropshire house in the hope that there may be some who, learning for the first time how easy it is to get to Stokesay, will not rest till they have paid it a visit.

The house is so commonly called Stokesay Castle that it would now be pedantry to call it by any other name. It is not, of course, a castle at all, but a fortified mansion. As an example of a purely domestic building which has been fortified it is, perhaps, unequalled by any other mediæval building in England; and it is so simple in its parts, and on so small a scale, that you can, so to speak, grasp the meaning of the building at a glance. This, I take it, should be a recommendation to young architectural students to visit Stokesay.



To get there you go to Craven Arms Station, on the Great Western line, between Shrewsbury and Hereford. From the station the house is distant about half a mile. It lies quite close to the railway. As you go south from Craven Arms you can get an excellent view of Stokesay Castle from the railway carriage window to your left. Few persons notice it, I fancy. It does not make itself conspicuous, and for my own part I must have passed it more than once before I was aware of its proximity.

If you are a cyclist and are touring in Shropshire you will probably visit Ludlow. Ludlow lays claim to be the most picturesque town in England, and with some reason. When you have satisfied yourself with the reasonableness, or otherwise, of this claim, push on about seven miles along the road towards Shrewsbury, and you will come to Stokesay. In Leland's *Itinerary* we read, "Aboot V miles owt of Ludlo, betwixt Ludlo and Bishop Castle, Stoke Say belonging sometime to the Ludlos, now to the Vernons, builded like a castell." Leland's five miles are now seven.

The house is beautifully situated. It lies in a valley with gently rising hills around it. A pond lies between it and the railway, and the road runs between the house and this pond. But in all probability you will approach the house from the churchyard, and the first view seen from that point will strike you with a cheering restfulness, and a sense of unique beauty. What is the peculiar charm of Stokesay Castle it would be difficult to say. I think colour and proportion are the keys to the puzzle. Seen for the first time on a summer's evening just before the sun disappears, the picture left on your mind is one that will not pass away for many a day, not even should it be weakened for a moment next morning in a blaze of Shropshire sunshine.

By all means see Stokesay first in the late afternoon. The somnolence and lethargy of Shropshire seem to have settled down there. You enter through the black and white Elizabethan gate-house into a grass-covered court. You pay an entrance fee of sixpence, and then can wander about as you like. There are no "guides" to bother you, and to tell you that Queen Elizabeth slept here. But that is probably because there is no bed to be pointed to. You can, if you wish, for another sixpence purchase an excellent little handbook to Stokesay by the late Mr. Thomas Wright, F.S.A., and thus armed you can examine the old house at your leisure. There is another handbook sold in the district, written by the Rev. J. D. La Touche, vicar of Stokesay. Both these little books are to be recommended to anyone wishing to understand the building. They give its history, and point out all its architectural features.

The house occupies the whole of the western side of the courtyard, and is immediately opposite to you as you enter from the gate-house. The whole site is about 150ft. square (a very irregular "square" however) and is entirely surrounded by a moat about 20ft. wide. The moat was formerly supplied with water from the neighbouring pond, but is now dry, and is used as a kitchen garden. The Elizabethan gate-house recalls the black and white houses of Shrewsbury. It is a richly ornamented timber

SKETCH PLAN OF STOKESAY CASTLE.

building of two storeys, the upper one of which projects considerably over that below. The photograph shows the side of the gate-house facing the courtyard. Did this old house stand quite by itself, it would doubtless receive more attention from the wandering tourist than it is ever likely to do as a mere appendage to Stokesay Castle.

The house itself falls naturally into three parts. The hall in the centre, the northern tower, and the curious polygonal tower at the south end. The two towers are each of three storeys, though the roof of the northern tower is not higher than that of the hall, of which, indeed, it is now a continuation. This northern tower was in all probability originally finished with a stone battlement, which has been removed to make way for the picturesque overhanging timber structure which forms so prominent a feature in the view of the castle from the north-west angle.

The licence to crenellate Stokesay is dated 1291. The south tower must have been built subsequent to this date, and the hall and north tower are no doubt much earlier. The house, then, was not built all at one time. Indeed, the three parts into which it naturally falls would appear to have been built at three different periods.

The great hall is 53ft. long by 31ft. wide. It is a fine specimen of thirteenth-century architecture, and has not been spoiled by over-restoration. It is lighted by four large windows on the western side, and three similar windows overlooking the courtyard. They are two-light pointed windows with a plain circle in the head. Over each window is a gable, which breaks up the long line of the hall roof in a very happy fashion. The hall is lofty, and has a fine collar-beam roof with curved braces. The steps of the staircase on the north end, leading to the rooms in the tower, are cut out of solid blocks of oak.

The south tower, which forms so remarkable a feature in all views of Stokesay, is detached from the rest of the house, being connected with it by a passage-way only. Access was also obtained by means of a covered way on the courtyard side, from the withdrawing room at the southern end of the hall. This covered way no longer exists, but the line of the roof may be seen on the wall following the rake of the steps.

The tower is very unusual in form. It is described as "an irregular polygon of twelve sides and about 30ft. in diameter, and presenting externally the appearance of a double octagon tower." It is divided into three storeys, and lighted by narrow loop-hole windows, which have all had interior shutters and fastenings. The roof is now a lead flat, from which a most delightful view of the surrounding country may be obtained. Looking down on the old house beneath you, the colour of the roofs is something to rejoice over.

At the south end of the great hall, on a "first-floor" level, is the withdrawing room, an erstwhile handsome apartment with a very fine seventeenth-century chimneypiece in carved oak. This room has two small windows looking into the great hall.

The chief interest of Stokesay is that it remains to-day so perfect an example of a fortified domestic building. Haddon Hall is perhaps the best place in England to study the gradual growth of domestic architecture. The changes from Norman to Jacobean times can all be followed there in the arrangements and details of the house. Stokesay is a smaller and much more modest building. But it had a licence to crenellate, which Haddon never had. It has a history of battle and deeds of war, for which we look in vain at Haddon, where the sound of fighting was never heard.

There was some connection between the two houses at one period. The Vernons, mentioned by Leland, were a branch of the family of Haddon. For many years Stokesay belonged to the Ludlow family. John Ludlow, the last of the male line, who succeeded in 1498,

STOKESAY CASTLE AND CHURCH FROM THE SOUTH-WEST.

left two daughters, co-heiresses, one of whom, Anne, was married to Thomas Vernon, son of Sir Richard Vernon, of Haddon. She received Stokesay as her portion, and the Vernons made the house their residence for three generations.

What the house looked like in the middle ages we can only surmise. The wall round the courtyard would be high enough for defence, as we now see it against the south tower. There were other buildings in the courtyard itself, which have now disappeared. And the gate-house, if gate-house there were, would be something very different from the picturesque building of to-day.

From the south-west, looking at the castle from the railway or from across the pond, the tower of the parish church fastens itself on to the old house in a not unpleasing fashion. This is the best known view of Stokesay, though I venture to think that the view from the churchyard, embracing as it does the gate-house and the full extent of the building, is more striking and impressive.

Nowhere, perhaps, is a building more in harmony with its surroundings than is Stokesay Castle. It seems to have grown naturally from the soil, and the sleepy drowsiness of Shropshire is in its stones. The days of battle are over, and the old house is having a long rest. But time has touched it with so kind a hand that we feel no regret for past glories and present decay, but only thankfulness that we can enjoy the picture of so noble an old age.

STOKESAY CASTLE: NORTH-WEST ANGLE.

HOUSING AT BIRMINGHAM.

BUILDINGS ON THE MILK STREET SITE.

In Milk Street, Birmingham, the Estates Committee of the Corporation have just finished a number of labourers' cottages, the cost of which, calculated upon the basis of living rooms only, works out at about £62 per room; but if the sculleries, &c., are included the cost is reduced to £45 per room inclusive—figures which are regarded as most satisfactory. The site has a frontage to Milk Street of 294ft., and to Little Anne Street of 185ft., and upon this area 56 labourers' cottages and five artisans' dwellings have been erected, which, with those already built in Ryder Street and Lawrence Street, bring the total number of such dwellings now in the possession of the Corporation up to 164. The labourers' cottages are two storeys high, each house being self-contained, with living room, bedroom, and the necessary offices on the same floor. Those on the upper storey are fronted by a substantial balcony with iron railings, and are approached by a stone staircase 4ft. 6in. wide. Twenty-four of the cottages have each one living room, averaging 13ft. by 14ft. and 8ft. 6in. high, and bedroom averaging 12ft. 2in. by 9ft. 6in.; the remaining 32 houses having a living room 13ft. 4in. by 14ft., one bedroom 8ft. 2in. by 14ft., and an additional bedroom 9ft. by 9ft.—all of the same height, 8ft. 6in. Each tenement has its own scullery, food pantry (with ventilation by means of air-bricks), and other necessary accommodation, and the houses in the upper storey are fitted with dust-shoots, so that there is no necessity to leave the dwelling for ordinary household work. Each tenement is divided by a 9in. brick wall, the walls between the living room and the bedroom being constructed of 4½in. brickwork. This scheme is maintained throughout with the exception of the five artisans' dwellings, which have each two bedrooms, the division walls of which are either of plaster and metal lathing, or of lath and plaster. The cottages front on Milk Street and Little Anne Street, whilst at the rear is a large open space, 30ft. wide, paved with blue bricks. Each house has its own closet, with flushing cistern, the sewers are ventilated, and the general sanitary arrangements excellent. There is a concrete foundation under all the walls, and the latter, of unpressed bricks, are built in Flemish bond. The buildings have been erected by Messrs. B. Whitehouse and Sons, of Monument Road, to the designs of Mr. J. Tart, the manager of the Estates Department. The cost of the site was £6,000, and the buildings, including sewers, drains, roads, concrete foundations, &c., £10,100. The houses let at an average rate of 1s. 6d. per week per living room, and the gross annual income is estimated at £659 2s., from which there will be the customary one-third allowance for rates, water, and voids and repairs. The new houses have materially improved the character of the neighbourhood.

STOKESAY CASTLE FROM THE COURTYARD.

THE DRAINAGE OF A HOUSE.*

By R. ELSEY SMITH,
Professor of Architecture, King's College, London.

The subject of this evening's lecture is the "Drainage of a House." In dealing with the drainage arrangements of a new house more than one type must be considered. The detached house, standing in its own ground, usually met with in the country; the semi-detached house, with a more or less narrow passage on one side; and the regular terrace house common to London and most large towns. The detached or semi-detached house offers in most respects the easiest problem for a perfectly satisfactory drainage treatment, and we may profitably consider it first in detail and afterwards deal briefly with the special difficulties imposed by the unavoidable conditions of city life.

I do not propose to consider this evening such exceptional methods of drainage as are advocated by Professor Poore, which, however successful, are only capable of being adopted in somewhat exceptional circumstances, but shall confine my remarks to the methods of drainage generally accepted as suitable to a water-borne sewage system, whether it be connected with a discharge on to open ground, with cesspool, or a public sewer.

Properly, the question of drainage is one of the first points to be considered in the planning of a new house, and it is a question that may affect its construction materially, and should be considered in conjunction with the situation and fitting up of the various sanitary conveniences.

A house cannot be satisfactorily built in such a situation that it is impossible to drain it properly, and the question of proper drainage will depend very largely on its destination, which, if it is to be discharged into a public sewer, is rigidly fixed and has an important bearing on the level of the lowest storey of the house. This must be constructed as a rule at such a level that the drainage may be conveyed away by gravitation by means of a drain having a certain definite fall as a minimum.

It is most undesirable that even cellars used only for storage purposes should be constructed to such a depth that they cannot be properly

* Lecture delivered at the Carpenters' Hall on October 25th, 1900.

drained by gravitation; but this cannot be always avoided, and in many cases such cellars, if care is taken to make them water-tight, may be satisfactorily used; but if constructed carelessly, or if the waterproof lining is ruptured by a settlement, such a cellar may cause an infinity of trouble and expense. The first consideration, therefore, in arranging the drainage of any building is to ascertain the destination of the sewage and the level at which it must be delivered. It is then possible, making allowance for distance and proper fall, to arrive at the level of the lowest point that can be properly drained and to make the necessary disposition of the building accordingly; but I would impress upon any of you the importance in dealing with a new building of considering the drainage at an early stage, and of the extremely awkward results that may ensue from first constructing a building, and only when it is erected considering how it shall be drained.

But assuming that these matters have had proper consideration, and that the internal fittings are well arranged and well grouped, we have still to consider the actual planning of the drainage and various arrangements connected with it. In arranging a system of drainage we have to provide, firstly, for conveying away from the building—the liquid refuse from W.C.'s, sinks, baths and lavatories which is subject to putrefaction, and also the rainwater collected in wet weather by the roofs, and conveyed to the ground level by means of rainwater pipes; secondly, for preventing the sewer gas which is generated by the decomposition of the foul matter, which may be extremely injurious to health by finding its way back into the house; thirdly, for arranging that in the event of a stoppage occurring in any part of a drain it shall be possible to exactly locate it, and remove it with the least possible delay, and without interfering with the general drainage system.

These ends, remember, must all be attained without rendering the cost oppressive to the owner of the house, and the various appliances must be of such a character that, even if they are neglected for long periods or even misused, they will in the main still continue to act efficiently, as it is only rarely that householders can be induced to give regular attention to the cleansing of their drains.

What, then, are the materials at our disposal for the solving of this somewhat complex problem?

Take first of all the channel by means of which the liquid or semi-liquid matter is conveyed. This is of necessity in most cases some form of pipe, as apart from other objections, it would be often impossible to obtain a sufficient and regular fall with an open channel. These pipes require to be true and even, impervious, and of a material not liable to be acted upon by the acids contained in sewage, and at the same time readily handled. Glazed earthenware or stoneware are the most suitable for ordinary works, though iron pipes are sometimes employed, and are excellent except from the one point of view of expense.

Drain pipes are usually made circular in form and about 2ft. long, with a socket at one end in one piece with the pipe, though in certain exceptional cases loose bands are made for jointing pipes. Such pipes are made in several sizes from 3in. in clear internal diameter upwards. They are usually salt glazed, that is to say, the thin sheet of glass which renders them impervious is formed during the process of burning the pipes in the kiln. This is done by throwing salt into the kiln, which becomes volatilised and forms a glaze on the surface of the pipe, both internal and external, and has the great advantage of reaching all parts of the pipe. It is of great importance that this surface should be even, free from lumps which would tend to check the flow of sewage, or form cracks or pinholes, which would allow the liquids to escape, and the pipes employed for the highest class of work are usually tested under hydraulic pressure and stamped with a T by the manufacturer. The thickness of material in such pipes, if made of stoneware, is usually $\frac{9}{16}$ in. for 4in. drain, $\frac{11}{16}$in. for 6in. drain, for larger diameter $\frac{1}{12}$ of internal diameter.

In addition to ordinary straight pipes of uniform diameter, diminishing pipes are made so that when required the diameter of the drain may be reduced or enlarged from one size to another, and the sockets are provided as required at the large or small end of the pipe. On no account should a pipe of small diameter be jointed to a pipe of large diameter, except by means of a taper pipe. Various bends are made to curves of various radii in order to avoid abrupt changes of direction, but these should only be employed in the construction of rainwater drains; Y junctions also should only be employed in such drains. These are arranged to bring branches into the main drains or to bring two branches together, and are of various forms, but should be in all cases so arranged as not to discharge either stream of water at right angles to the flow of the pipe which it joins, as this is liable to cause a deposit of any solids carried along and an obstruction in the pipe. They should be joined to the main pipe at a rather acute angle, so that the two streams may unite and flow together. These Y-pipes do not necessarily have both branches of the Y of the same size, and they may vary considerably; thus a 4-in drain may be brought in to join one of very much larger diameter.

For all drains conveying solids such junctions are to be avoided, and connections should only be made by means of open channels in chambers specially arranged for the purpose; the reason being that all such drains are liable to stoppage, and if they are branched into another drain by means of a closed junction the difficulty of locating the stoppage is increased.

It may be well to point out that even drains conveying only rainwater are not absolutely free from solid matter, droppings from the mortar joints of parapets and chimneys, the droppings of birds and soot—all get washed off into the gutters, especially in heavy rains, and find their way into the drains, and if these have so slight a fall that the flow is very sluggish, they may be deposited in the drain and gradually block it. I have seen a drain taken up after a lapse of about a dozen years when more than half the sectional area of the pipe was choked with such deposit.

The open channels already referred to are also arranged so as to bring the sewage they carry into the main channel in such a manner that the flow may be checked as little as possible and may be delivered in the right direction, and they, like the bent pipes, are made to various curves of different radii. In many cases where the radius is small and the change of direction is therefore rapid; these are not merely half channels, but three-quarter channels, the edge in the outside of the curve being raised and curved over to prevent the stream of water shooting over; but it is desirable to avoid, if possible, very sharp curves in pipes carrying soil.

There are various methods of jointing such pipes so as to make a continuous drain: the old method used to be to place the two pipes together, the spigot end of one pipe inside the socket of the next below, and then make good the joint with clay. Such a joint is quite unable to withstand the severe tests to which drains are now subjected, and would therefore be liable to fail if the drain at any time was under pressure. A clay joint, moreover, is liable in many soils to dry up and crack and become leaky even within a few weeks of its formation.

The simplest form of joint now used is the cement joint, and if carefully made this is perfectly efficient. The two pipes to be jointed are placed in their true position, carefully centred, and the cement, which must not be so liquid as to run easily, is filled in round the joint—an operation requiring much care if it is to be well and uniformly filled all round; the joint is finished off externally with a sloping face.

Care must be taken to ensure that no cement is forced up between the two pipes so as to form a ridge, which might check the flow of sewage in the pipe, and when cement joints are used a badger is generally employed to clear them. This is a circular piece of wood smaller than the pipe, with a rubber edge, and having a wire handle attached; it is inserted before the joint is made and afterwards withdrawn, removing all cement that may have been forced up between the joint. Sometimes this is wiped out with a cloth. For this reason it is most undesirable to joint up two pipes before laying them in the trench, as the section thus formed is too long to allow the internal joint to be reached.

THE GREAT HALL, STOKESAY CASTLE.

Other joints depend on the previous preparation of the spigot and socket by coating them with a preparation of asphalt cast on by means of dies, and so arranged that the pipes are self-centreing. Of these the best known is Stanford's joint, the patent for which has expired. In this joint the material (which is formed of 1 part of clean sharp sand, 1 part of boiled tar, and $1\frac{1}{2}$ part of sulphur) is made conical in form. It requires greasing before the joint is made, and care must be taken that the spigot is driven well home into the socket. This joint is sometimes finished externally with cement.

Another similar method of jointing is supplied by Messrs. Doulton, and is termed an adjustable joint, the band on the spigot having a carefully-formed curved surface; this joint also is fortified by an external ring of cement applied outside the joint.

Sykes' joint has the composition cast on in the form of a screw and nut, the two pipes being screwed together, a thin layer of cement composition being used, which is forced into all interstices by the screwing up of the joint.

There are more elaborate forms also used; a useful one, especially in wet situations, requires an extra deep socket and provides two

bands of such asphaltic composition with a clear space between them. After the joints are put together this space is filled up with liquid cement from a hole above, and provides a very strong and watertight joint.

There are some other points to be considered in relation to the laying of a drainpipe; but before touching on them I must point out that all we have done at present is to consider the formation of a pipe to carry away rainwater or sewage.

Sewage begins to decompose very rapidly, and in the process it gives off a gas that may prove extremely injurious to health, especially if it is introduced into an enclosed space such as a building. One of the objects to be attained in arranging a system of drainage, is to prevent this gas entering the house or other building. This is done by the use of traps; the oldest form of trap is the dip trap. This consists of a rectangular box inserted in the length of the drain with a division running across the upper half, and carried down low enough to dip into the water that will always be retained in the lower part of the box. This is the principle of all traps, and consists, you will see, in placing in the course of the drain an obstruction which, while it allows the sewage to pass under it, interposes an obstacle to the return of air from the lower part of the drain.

The principle is correct, but the special form above described is in practice to be condemned; the box form offers a receptacle in which any solids contained in the sewage are apt to be deposited; it checks the flow of sewage, and if not very well constructed is apt to be leaky.

The intercepting trap is a development of the same principle but with all the drawbacks of the dip trap eliminated as far as possible. It is made of the same material as the ordinary drain pipe, and constructed so that its lower end can be jointed into the drain below; the upper end has a flange or half socket to receive an open channel from the drain above. The trap is usually made to dip sharply and to rise with a more gradual slope, and where there is no difficulty about falls, it is desirable that the upper side should have a cascade; that is to say, the upper arm is kept at a slightly higher level than the lower to give increased impetus to the flow so as to clear the trap well.

Between the outlet and inlet the upper part of the trap dips down somewhat in the form of a lip, to a considerable depth below the level of the outlet, so that it is at all times submerged to a depth of at least 2 to 3in. by the water which is retained in the dip, thus "sealing" the trap as it is termed and performing the part of the dipper in the old trap. It is usual to add to this form of trap a cleaning eye, so that rods can be passed down the drain from above in case of an obstruction, and this eye is closed by a stopper hermetically sealed.

The very best of such traps inevitably put some check on the flow of sewage, and it therefore happens that obstructions, if liable to occur, generally take place at the trap, and under these conditions, the chamber in which the trap is placed may become charged with sewage and much difficulty experienced in clearing the obstruction. To meet this, in some of the best traps an additional opening is provided above the cleaning eye, closed by a heavy stopper with a chain attached, which is secured to the top of the chamber so that it can on occasion be raised when the chamber is full, allowing the contents to flow away through the cleaning eye.

Such a trap as has been described is used in the main lines of drainage to intercept the return of the sewer gas from the main sewer into the drainage system; but within the system itself such gas may be given off or the intercepting trap may fail to act on some occasion and further safeguards are required.

These are supplied by gullies, which are traps of varying forms arranged to disconnect the rainwater and other pipes from direct communication with the drains. Though differing in form in many different directions, the principle of all is the same; they consist of a chamber open at the top to the outer air and covered by an open grating and adapted to receive the water discharged from one or more rainwater pipes or wastes which may be connected to apertures in the body of the gully, arranged so as to be above the water level or may be simply discharged above the grating covering the chamber.

If the gully is to receive liquid matter only, it is formed something like an intercepting trap, the outlet being at the bottom with an arm rising sufficiently to secure an efficient seal. Such a gully should be self-cleansing, and therefore free from any square angles. One form of such gully much used now is the channel gully, which has a large head forming a channel into which the down-pipes and wastes may be discharged, the object being to remove the discharging pipes from a position immediately over the body of the gully, so that in case of its failure from any cause to intercept the sewer gas, it will be less likely to find its way into the pipe and thence into the house. Such a gully, and some other forms also, are made in two pieces, allowing of ready adjustment both to the drain and the rainwater pipes and wastes.

If solids are liable to be brought down with the liquids it is often desirable to prevent them from entering the drain, excepting, of course, in dealing with soil pipes, and in that case the body is deepened to form a pocket into which they will be deposited—the outlet and trap being placed at one side. This is the principle of the road or yard gully where a large chamber is provided to catch the grit washed off the roads, which is from time to time dug out.

A special form of receptacle and trap is required to receive the waste from scullery sinks which is apt to be charged with grease, as, if allowed to enter the drain, this is liable as it cools to congeal and clog the drain. The simplest form of trap for such a position has a central sinking in which stands a dipper, in the form of a metal box with a long handle, and a very deep seal is provided. The trap is larger than most, contains a considerable body of water which will normally be cold, and as the warm discharge from the sink enters rapidly chills it, the grease, or most of it, floating in the centre of the trap, and not passing into the drain. It is removed by raising the dipper which fits the gully and brings out the refuse with it, and after cleaning is returned. This form of trap is open to the objection that it requires frequent attention to remove the grease that collects, which rapidly becomes putrid, and it cannot therefore be considered as by any means a perfect arrangement.

A better but more expensive arrangement is the flushing grease trap. This consists of an earthenware chamber with a deep seal trap at the outlet, and with a loose top capable of being securely fixed but removable for occasional cleansing, and provided with a flushing rim and inlet, as well as inlet from sink. A flushing tank, 20gals. at least, with a head of water not less than 7ft., should be provided and fixed, if possible, inside the house, and should be made to discharge automatically at fixed intervals, say twice a day, or oftener if the sink is much used. On discharging part of the water is conveyed to the flushing rim, part conveyed direct down to scour out the bottom of the trap. The action here is that the flush breaks up the congealed scum into small pieces and forces it through the drain, and being already congealed it is not liable to adhere to the sides of the drain.

Another somewhat simpler form of grease trap is also used, which has also a flushing rim, but with a grating over it; this is made in two or three pieces, and the receptacle being circular the different parts can be adjusted separately to accommodate the drain, the inlets from sink or sinks, and the inlet from flushing tank.

I would remind you of what was told you about the traps used by plumbers and their liability to failure from—1st forcing of seal, 2nd syphoning out, 3rd evaporation.

The first may happen to the intercepting trap; but, as already stated, should not occur to any gully in a well ventilated drainage system, neither should syphoning; but circumstances may arise under which either of these causes of failure will come into action.

The most frequent danger of failure, however, in the traps connected with a system of drainage, as distinct from those in a system of plumbing, is the failure from evaporation. Such traps have a rather large water area directly open to external air, and in cases where they happen to have no discharge from rainwater pipe or waste through a considerable period, the water may evaporate to such an extent as to destroy the seal. This may easily arise from the disuse of some internal fitting or from a long spell of dry weather.

With one exception the most dangerous position for such a gully is a small external area to a window which can at no time receive much rainfall, and it is desirable in any such position to take into the same gully the discharge from a bath or lavatory in constant use. The most dangerous situation of all is that in which a gully is required to be placed inside an internal cellar or basement to drain it when occasionally washed down. Such gulleys should be avoided if possible; if this cannot be done some special precautions should be taken, the best being to cut off the drain by means of a valve only opened when the cellar is cleaned; but even this is not perfect as its utility depends upon the valve being properly closed.

We have still to consider the methods to be adopted for locating any stoppage, and removing it, before we consider the actual laying of the drain. This is provided for partly by the use of manholes, and partly by taking care that all connections are made in such manholes, and that the drains between them are laid to perfectly even falls and in truly straight lines.

A manhole is a chamber usually built of 9-in. brickwork on a concrete foundation, and should not, if more than 1ft. 6in. deep, be of less clear internal size than 2ft. 6in. by 3ft., or it becomes difficult to use cleaning rods; and if many connections are required it may be considerably larger. Such chambers are of two kinds, 1st the intercepting chamber, 2nd the inspecting chamber.

An intercepting chamber is always placed between the drainage system and a public sewer or cesspool; it is always on the land belonging to the house to be drained, but as near the sewer as this condition will allow. In the wall next the sewer is inserted an intercepting trap already described, and through the manhole the main drain is conducted in an open channel. This is usually half round in section, and of glazed earthenware, but is sometimes formed in the concrete and rendered, but the first is more cleanly. This channel, which may with advantage be laid to a sharper fall than the drain itself, is made good to the trap at one end and at the other to the drain, and above the channel the concrete is banked up steeply and rendered in fine Portland cement, which should be continued for 12in. up the walls at least, unless the chamber is lined with glazed bricks. If additional drains have also to be brought into this chamber, they are conducted by means of the curved channels already described so as to discharge into the main channel. They should on no account be brought into the manhole high up and allowed to discharge in a cascade. Specially-made earthenware bottoms to the whole chamber are now sometimes used, thus avoiding any cement work, and ensuring greater cleanliness. If the chamber is deep, climbing irons must be built in for access—either purpose-made iron steps or a length of iron gaspipe built in diagonally across one angle. The chamber is usually roofed with a slab of stone carefully bedded and jointed all round, and perforated and fitted with an air-tight manhole cover which can be locked in position where access is not required. Such a chamber must have a fresh-air inlet, which will be referred to later. In a country house, where the intercepting chamber is a long way from the building, it sometimes has an open grating instead of an air-tight cover. An inspection chamber is similar in all respects except that it has no trap and no fresh-air inlet. Such chambers are placed wherever most convenient, and are provided wherever the principal drain changes its direction, or where it is desired to collect together several single pipes. They may with advantage have at the outlet a special pipe with an enlarged end to facilitate the use of cleaning rods. Such chambers should not in any case be more

than 80yds. apart unless an intermediate lamp-hole is provided. In towns such distances are rarely encountered, but they may well occur in dealing with a country house. Lamp holes, which must only be inserted in straight lines of pipe—never in bends—consist usually of an upright pipe of the required length, 6in. diameter, and with an iron frame at the top; they are merely used for lowering a lamp or candle when it is desired to examine the drain.

We have now dealt with the various component parts of the drain; let us look at the method of bringing them all together into a complete drainage system, first of all on paper in planning them, and afterwards in construction.

Take an ordinary double frontage semi-detached house. The first thing to do is to ascertain the position and level of the sewer, and the level of the lowest point of the premises you have to drain, and ascertain the length of run approximately; if there is an amply sufficient fall for your purpose, say 1ft. in 40 or upwards, you may start from the head of the drain, and lay out your levels without any anxiety.

It is not essential that a drain should have a uniform fall throughout its entire length, but it is essential that the fall of each separate length be uniform from manhole to manhole; and bearing this in mind the drain should be laid out so as to entail the least amount of digging possible, and with the smallest efficient fall. It is important to start with an inspection chamber near the head of the drain. The invert may be arranged about 2ft. or a little more below the ground, unless it is liable to be exposed to moving loads above it; fix the level as so much below the level of ground floor or some fixed datum. Then lay out the drain to the next manhole, allowing a fall of 1 in 40 for a 4in. drain, or 1 in 60 for a 6in. These falls are enough to maintain a flow of 3ft. per second, and to render the drain self-cleansing, and should not be increased beyond 1 in 35 for 4in., or 1 in 45 for 6in., or the result will be for the liquid to run off too fast and deposit solids in drain instead of carrying them along; but as already stated, the channels in the intercepting chamber may be given a more rapid fall, say 1 in 12, to give extra velocity to the sewage before it enters the trap. The exact level of each manhole should be calculated, in reference to the datum first used, and figured. When the intercepting chamber is reached, the remainder of the drain may be given a steeper fall from this point direct to the sewer.

If you have, on the other hand, little to spare in height, it is well to start from the intercepting chamber and work backwards to the head of the drain. In laying out the drains of such a house they must be so contrived as nowhere to pass under the building itself. It is necessary also to provide for ventilating the drain. If this is not done gases may collect in the drains, and will exert a pressure upon the traps, and if the accumulation continues, and the pressure increases, may force the seal of one or more of them.

The usual system is to provide for letting in a current of fresh air at the intercepting chamber and providing, at the head of the drain, a ventilating pipe, carried up the full height of the building, and at least 3ft. above the level of the eaves, or, if there are dormers, 3ft. above the top of the highest window. If this soil pipe comes within 10ft. of head of drain, this may be used as the ventilating pipe, otherwise a special pipe must be provided. The inlet usually has a square boxhead, closed by valves of mica, to prevent its acting as an outlet. The outlet should have a wire dome fixed to the top, in order to prevent birds from building in it, and stopping its action. With such an arrangement in working order it is impossible for gases to accumulate so as to exert a pressure upon the traps, as they would escape from the outlet at a point where they would be innocuous to the inhabitants, but the inlet in particular is liable to get out of order, if not attended to, as the pivot on which the mica valves work may corrode and stick.

The fresh-air inlet is usually kept low down, while the ventilating shaft is carried up to above the roof level; and the theory of this arrangement is that the difference in the length of the two pipes will stimulate a flow of air through them and the intermediate drain. If it is possible to fix the ventilating pipe on the south side of the house, where it catches the sun and is warmed, such action is no doubt assisted during the periods of sunshine; the column of air in the pipe will at such times be heated, and tend to rise, but this action cannot be relied on in all weathers; it does, however, at all times provide a free outlet for any vapours arising in the pipes. In some special cases it is permissible to reverse the positions of the fresh air inlet and the ventilating pipe.

The actual construction of a drain is not a very difficult matter, but requires care and supervision. The necessary excavation must first be made, and the levels at the various points tested. A layer of concrete not less than 4in and usually 6in. thick, is spread over the floor of the trench, and is made from 9in. to 12in. thick under the manholes; the syphons, channels, and inlets to the manholes are then placed in position and bedded and the walls afterwards built up and the laying of the pipe drain between manhole and manhole is proceeded with. It is of great importance that pipes should be laid not only in a straight line on plan, but to a true fall in section, otherwise it would be impossible to look through the drain to detect obstructions, and in addition to the levelling of the concrete-bed each pipe is adjusted with a level. This may be an ordinary level placed on a special gradient block, the lower edge adjusted to the required edge, or an adjustable gradient indicator may be used. The pipes should be blocked up with bricks, or better, with special blocks, while the joints are made, and when a length is completed between two manholes it should be tested and afterwards concrete should be carefully filled in around the pipes, care being taken not to jar them or crack the joints. When concreting is finished and set a further test should be made.

The whole of the drains are thus laid; the end of each should terminate at a manhole or at a gully or be connected direct without any trap to the soil pipe or ventilating pipe. Any drain so laid is capable of being cleaned throughout its whole length by means of jointed rods worked from the manholes; if, on the other hand, one drain is jointed into another and an obstruction arises, it cannot readily be reached for cleaning without breaking up the ground. Where a drain runs between two manholes, a light may be lowered into one and from the other it will be possible to look down the drain and detect any obstruction.

In arranging the plan of drainage it is necessary to determine the size of drains to be used in various positions. It used to be customary to put in needlessly large drains, but it is now well understood that the smaller the drain, provided it will accommodate the maximum flow, the better. It is found in all respects better for a drain of small diameter to run nearly full than for the same amount of sewage to very partially fill the lower part of a drain of larger diameter, and at most times a "4-in." drain would suffice for even a large house were it not for the consideration of storms of rain.

The daily supply of water per head for all purposes is reckoned variously according to the class of house, from 8 or 10 gallons up to 50 or 60, and may be taken as a rule at about 30 gals., so that in a house containing ten inmates the daily flow of sewage would amount to about 300 gals. A 4-in. pipe, in which the sewage flows at the rate of 3ft. per second, will, when flowing half full, carry 50 gals. per minute, and a 6-in. pipe, at the same velocity and half full, will carry 115 gals.

If we consider the rainfall in addition, and assume we have to provide for draining a plot 25ft. by 80ft., or an area of 2,000ft. super., we find that an inch of rain will result in a downfall of 1,040 gallons in this area. In a heavy thunderstorm in England such an amount of rain may fall within half an hour, but a 4in. pipe flowing only half full should suffice to discharge this amount of water in 21 minutes, and would do so in the case of a straight pipe without obstruction, but in practice the interruption caused by manholes and changes of direction check the flow considerably, and where such a volume of water is to be dealt with a 6-inch pipe would be desirable. It may happen that with the utmost care in setting out the work circumstances make it impossible to secure enough fall to insure a velocity of 3 feet per second; in that case the drain cannot be relied on to be self-cleansing, and it is desirable to provide for periodically flushing it out. In some of the suburban districts round London and elsewhere a separate set of sewers is provided for rainwater, and the rainwater drainage is kept distinct from all sewage and soiled water, and in such cases a similar arrangement is equally necessary for dealing with the sewage.

This is done by constructing a chamber at the head of the drain so as to form a cistern that is discharged automatically when the water in it reaches a certain level by syphoning out. The flow of water into the tank is regulated so as to occupy so many minutes or hours as the case may be, and the tank should have an outlet equal in diameter to that of the drain to be flushed, so that the discharge may practically fill the drain, and carry all obstructions before it. The water from a bath and pantry sink, but not from a scullery sink, may be used with many forms of flushing tanks as a supplementary flush, or in place of a supply from the main, or one or two rainwater pipes may be taken to discharge into such a tank, but such a supply can only be supplementary, as its regularity cannot of course be depended upon. In dealing with long-drainage systems a penstock may be usefully employed at

STOKESAY CASTLE: THE GATEHOUSE FROM THE COURTYARD.

intervals, especially at the inlet of intercepting chamber. This is a stout metal disc, which, when in use, closes the inlet, and is worked by a screw or by a spindle. If this is closed while the upper part of the drain is flushed the water will be retained, and banked up in the lower part of the drain, and can be released by raising the penstock; a compact body of water of considerable volume will then be discharged, and will efficiently flush the intercepting trap.

In dealing with terrace houses which are so constantly met with in London, even in the best parts of the West End, we are confronted with the difficulty that we are not able to drain the back of the house except by a drain passing under the house itself, save in those comparatively rare cases where there is a sewer at the back as well as the front, or where a system of combined drainage at the back is resorted to.

In such a case an inspection chamber should be formed at the back collecting the various drains, and a straight line of drain taken through to the front intercepting chamber. No connection whatever must be permitted within the house itself, and it is desirable that an arched opening should be formed in all walls through which the drain has to pass, so as to avoid any rupture of the drain-pipe in case of a settlement occuring to the walls. The pipe must be entirely cased in cement after it has been tested in the usual way.

In some cases of this kind the pipe running between the two chambers is constructed of heavy cast-iron socketed pipes, caulked with lead at the joints, as these are less liable than the best protected stone pipes to crack under a settlement and allow sewer gas to escape into the house.

Complete systems of iron drainage are now arranged for, with pipes, traps, inspection and intercepting chambers all constructed in heavy cast iron, jointed with sockets or flanges. In this system brick inspection chambers are formed as usual for access, but the actual chamber for connecting the drain pipes is quite small, merely a rectangular or circular enlargement of the pipe, with an air-tight cover, the junctions being cast on at the required angles. Such an arrangement is cleanly, which the best contrived chamber cannot always be; it offers no large receptacle in which sewage may lodge and decompose, and at the same time is easy of access; but the cost is higher than that of ordinary drainage.

We have assumed that in all cases our drainage is to be connected to a public sewer, but even within short distances of London cases are to be met with where there is no such public sewer in existence, and in many such cases a cesspool must be resorted to. A cesspool is an undesirable neighbour to a house, and should not be constructed within 100ft. of it; if used, great care must be taken in its construction and in providing for its cleansing.

It is most undesirable that such a chamber should be built dry, that is to say, without mortar, as this allows the liquid to soak into the surrounding land, contaminating it, and if there are any wells or streams in the district, such a cesspool may be the means of poisoning the water at a very considerable distance. Cesspools are best constructed of impervious bricks set in cement and backed with clay puddle; they should be easily accessible for cleansing, and of a form that is adapted to this end, all sharp angles being avoided.

All rain and surface water and bath wastes should be carefully excluded; but drains from soil pipes, lavatories and sinks, and laundries, if any, must be provided for, and sometimes stables and cow houses; exclusive of the two last items, the daily amount of sewage per inmate may be taken at 12gals., say 2 cubic ft., and the size of the cesspool required to contain the necessary amount of sewage for a household of so many inmates for a week may be readily calculated. Such a cesspool is best cleaned weekly, the contents being distributed as manure in land away from the house.

A cesspool must be cut off from the drainage of the house by an intercepter, and the house drain thoroughly ventilated. The cesspool also, if it has an air-tight cover, should have an outlet pipe to allow of the escape of air as it gradually fills, otherwise it must of necessity be forced through the trap into the drain. Care must be taken that such an outlet terminates where no harm can result from the escape of sewer gas.

In dealing with a large country house where no sewer is accessible, the sewage may be treated by land filtration or precipitation in certain circumstances, but such methods hardly come within the scope of this lecture.

I must refer briefly to the method of testing drains usually employed. The two most usual and important tests are the water test and the smoke test. The former is applied to all new drains, and consists in closing the lower end of the length to be tested by means of a stopper; this is sometimes in the shape of a disc with an india-rubber ring round it, which can be forced out so as to come in contact with this pipe all round; sometimes a bag is employed which is inserted into the drain and then extended by pumping in air.

The drain is then filled with water as high as the level of the lowest gully connected with the length, or as far as the next manhole if there is no connection, but the head of water should in no case exceed 10ft.; if this be exceeded the length of drain must be subdivided and tested separately. Care must be taken in filling that the gullies do not become air-locked, as a cushion of air is then formed which makes the test unreliable; this is prevented by inserting into each gully a piece of bent tube so as to connect the internal air-chamber with the outer air, giving it a means of escape as the water rises in the pipe.

When the drain is filled it is left for not less than half an hour, the level of the water being marked at the commencement of the test and again noted at its close. There should be no perceptible loss of water beyond an extremely trifling one, due to absorption by the new cement in the joints, which sometimes occurs. If any loss is noted the length of drain must be carefully examined for any dampness, and it is on this ground that it is so important that the pipes should be well above the concrete level during the test, as it makes any leak so much easier to observe. Any joints that show failure must be marked and made good, and the test repeated. Every joint-pipe must be thus tested. In a small system of drainage one test may suffice for the whole if the level of the gullies is uniform; but in many cases several separate tests are necessary.

The smoke test is applied partly to test the efficiency of the ventilation of the drain and partly the efficiency of joints made above ground, particularly those in the soil pipe. In the first case one or two smoke rockets are placed in the intercepting chamber and ignited, the cover being at once replaced; in a short while, if the system is efficient, the smoke will be seen issuing from the top of the ventilating pipe.

When the test is made for the purpose of determining if there are any unsound joints, the top of the ventilating pipe may be closed by a damp cloth or a drain plug, and all traps filled with water; the soil pipe is then charged with smoke by means of a rocket if short, or by forcing smoke in from a larger apparatus if required, care being taken that no smoke escapes except into the pipe. The smoke used has usually a strong, pungent smell, and if there is any escape it is at once detected, but may be difficult to locate unless it escapes in sufficient volume to be seen.

For testing old soil pipes to which there is no access without breaking open the drain, ferrets are often used; they are small vials containing a substance emitting a strong, pungent odour; they are attached to a string and passed through one of the traps with the flush from a W.C., an arrangement being made for breaking them in the pipe, when any leakage is quickly detected by the odour.

You may be called upon to inspect and report upon the drainage of an existing house, and I may perhaps usefully conclude with a few remarks on such duties.

You will have little difficulty in recognising whether the drainage system you are called in to inspect is modern or of an antiquated type. In the first case inspection will be easy, as manholes will be provided, and it should not be difficult to locate any stoppage or leak by careful observation in the first case and by the water test in the second. In the case of an obstruction it should be capable of removal without disturbing the drain by means of rods. In the case of a leak it is not possible to exactly locate it without opening the ground, but you can fix with certainty the limits within which it is to be searched for.

If on the other hand you find indications of an antiquated system—including an utter absence of manholes and no proper ventilation—a mere ventilating pipe to the soil pipe, without the provision of a fresh-air inlet, is not efficient, your task will be more difficult. It will be necessary to have the ground opened to reach the drain in order to test it, and you will be fortunate if in such a case you find any plan of the drains to assist in the search. You may expect to find that the drains will not stand the water test, and in that case to comply with modern requirements, it is necessary to have them grubbed up and relaid. It does not necessarily follow that a drain that will not stand this test is, if in other respects well-designed under ordinary conditions, defective, but it is not a drain that can be relied upon, and if at any time a stoppage occurs in this drain and the sewage is thereby banked up and retained in the pipes the conditions become similar to those under which the test is applied and leakage is sure to occur.

Whenever drains are relaid care should be taken to make them comply with modern conditions. Not only should manholes be provided, but irregularities in the line and fall corrected; but in such a case the level of the lowest part of the building and of the sewer is rigidly fixed, and the drain must be laid out so as to secure the best fall compatible with existing conditions.

With an old drainage system you are liable to encounter pipes branched into other pipes, not by means of a proper eye, but by means of a hole cut into the pipe and made good with cement. This is almost sure to be a right-angle junction and defective. There may also be a dip somewhere in a pipe, otherwise sound, which will cause a deposit and ultimate blocking of the pipe.

Examine carefully all traps throughout; ascertain that the intercepting trap and also the gullies have a proper depth of seal, and that there is a proper provision for preventing the gullies becoming unsealed by evaporation. If a grease trap is used for scullery, ascertain what means of flushing it is used; and if there is none, if any provision is made for cleansing it at regular intervals.

Satisfy yourself that the ventilating system is properly designed and is in efficient working order, and that the connection between the soil and drain pipe is properly made, and that all rainwater pipes, bath, lavatory and sink wastes and overflows are disconnected by means of gullies.

Remember that redraining a house is a costly and troublesome process, and be quite clear that there is good reason for requiring the execution of such work; but, on the other hand, do not forget that bad drainage may mean bad health and loss of life, and that you are not doing justice to the owner or occupier, and may incur serious personal responsibility, if actual defects are overlooked in such an inspection.

The Hall of Fame of New York University, which is built in the form of an open colonnade in the university grounds at Morris Heights, overlooking the Hudson, is approaching completion, and the judges, consisting of justices, publicists, professors, and university presidents, have already begun to select the immortals who are to occupy this noble hall. One of the conditions is that they must have been dead at least ten years.

A new Wesleyan Church, at Herne Hill was opened recently. Accommodation is provided for over 600, and there are two vestries and a large church parlour for classroom and tea meetings. The church is of red brick and stone dressings. The architects are Messrs. Gordon and Gunton, of Finsbury House, Blomfield Street, E.C., and the builder is Mr. W. V. Goad, of Camberwell Road, S.E. The general foreman of works was Mr. T. C. Dickinson, of Albert Road, Peckham, S.E.

HOLBORN-STRAND STREET.

CRITICISM OF THE DESIGNS.

THE drawings submitted by the eight selected architects for the Holborn to the Strand street are now on view at the Royal Water Colour Society's Gallery in Pall Mall, and will well repay the trouble of a careful inspection.

The problem for which a solution was desired is of a complex nature, the portion selected for treatment being the base of the new street, where the avenue bifurcates and leaves a great island opposite St. Mary's Church. All the competitors have naturally selected this latter position for the proposed County Buildings, while a portion of this has already been allocated by the Act of Parliament for a specific purpose contingent upon the improvement.

The plan then roughly presents a vast crescent, dividing the traffic and giving a noble entry into the Strand, westerly to Waterloo Bridge and easterly by St. Clement Dane's Church. It will thus be readily seen that a very great opportunity was given to originality of design, but this had to be chastened by practical and consistent regard for commercial considerations.

All that was asked for were elaborations of the façades and a block plan. To our junior professionals this would open a pleasurable vista, but to the matured architect a very grave aspect was added to the problem in the alteration of elevation from plan, a dictum which will not hold good even in these days of Classical revival; hence much difficulty was experienced.

The result of this "concours" can therefore only be of a tentative and suggestive nature, and affords but a general idea of what the ultimate result may be. Several reflections present themselves to the visitor, one the enormous amount of work which has been done and the clear presentation of the several individualities of the several competitors, although only designated by numbers. Looking at the exhibition as a whole, it will be, no doubt, considered that the majority have failed to grasp the great civic idea. It would be comparatively easy to foresee what eight selected Parisian architects would have proposed, and the complete sympathy that they would have expressed as compared with any attempt which could be made in London.

The architectural character which was suggested was "Palladian," and it is somewhat curious to note what this term conveys to the minds of some of our men of light and leading. We note the wisdom of the London County Council in thus formulating their wishes; but the term with our architects seems to be somewhat elastic, and very great latitude has been assumed by several competitors, while the general term covered by all would be nearer being "Palatial."

Conditions were laid down as to draughtsmanship, as a flat wash of ink for the window and door openings; but No. 29 gives a pretty washed effect, and No. 27 varies his tones and adds body-colour to a pen-and-ink sketch effect, both taking an unjust and uncalled-for advantage over conductors and competitors.

Entering the gallery on the left hand is No. 23, whose personality stands at the top of his profession; and it is reported that this is the first competition he has entered for since his R.A Gold Medal days. This gentleman breaks his plan up into various blocks. The public building has the look of a ducal abode, the others grouping around. The new street does not seem to come happily into the scheme: two avenues are provided, and the theatre treatment is good. The whole scheme is uncivic, and there is an amount of freedom which the individuality of the author has expressed in a general disregard for the conventionalities of proportion; the drawings are clear and free from any affectation of display, and may be designated as clear and plain.

No. 26 is the work of one of our most successful men known to everybody, and the design is generally admitted as the most satisfactory exposition of the problem. It is, in fact, the civic idea focussed with great skill in appropriate surroundings, the whole in one key. The character is in harmony with Somerset House and St Mary's Church. The principal entrance to the County Building is, however, at the bottom of the new street, which, when fully considered, will be found to be from every consideration the most desirable and, in point of vista, the most notable.

This has been admirably conceived by the skilful introduction of a grand quadrant flanked by towers and united by a fine screen wall, a dome—the only one introduced—being in the centre. Two avenues lead into the Strand, and these are connected with the main front by fine colonnades over wide spanning arches.

The Strand front is broadly treated, the buildings on either side of the avenues corresponding, but differentiated from the County Building. This latter has pedimented wings, and the central portion is a great flat curve which again brings out the dome as the dominant feature. In the County Building there is a broad and pleasurable feeling of wall space; the lighting spaces may in some instances be considered small, but as plan must govern and limit future possibilities, it is needless to criticise any separate features which can only be considered as suggestive. In this particular case, however, the whole lay out is admirable, and a definite idea is presented. It is needless to say, as always, the author of No. 26 has given drawings beautifully rendered, clean, crisp, and free from affectation.

In No. 21 we come to the commendable effort of one of our distinguished literary architects, who is strong both with pen and pencil. In the plan no definite line has been adopted beyond the inclusion of two avenues.

The treatment is brick and stone of the school of Wren, and the full advantage of height has been made use of. This was put as a limit, and it would not appear to have been a *sine quâ non*. The civic note is, however, lacking, notwithstanding the interest of parts, and a feeling of monotony supervenes, with a suggestion of first-class dwellings decoratively treated.

From the commercial aspect, however, No. 21 will certainly commend itself, notwithstanding the aggregation of rows of sash windows supervening without band or string, while the frequent repetition of certain defined decorative features will not yield the happiest result.

The drawings are thoroughly worked out, and the author's well known hand feelingly employed.

In No. 19 we have no doubt the architect of the Sessions House, and we find corresponding character. The plan is well arranged, with an internal court entered from the Strand, and parted therefrom by a colonnade; two avenues are provided on either side. The whole is treated in a severe phase of the Sessions House manner, and would make excellent Courts of Justice. Needless to say a fine dome occupies the centre flanked by noble campaniles, and smaller domes at each end of stunted proportions. Long straight lines have been maintained, but the tone is lost on the other buildings in which the wall surface is overloaded with arches and coupled pilasters. The whole is set upon a sparrow-pecked rusticated base; the character of the design is Chambersesque, and is the most severe in the gallery.

No. 29 is a brilliant effort by a clever Gothicist; the draughtsmanship is also clearly by another well-known hand, who is facile at this character of work.

The plan is decidedly striking, and provides a great quadrant to the Strand front, with a carriage drive recessed from the street. Two avenues give access from the new road, with steps down; and a fountain is placed at the parting of the road, with terraces upon either side. St. Mary's Church is shown upon the Strand elevation, and a fine horizontal treatment is maintained throughout.

The character is that modern rendering of Palladian which is finding favour, while parts are reminiscent of a former competition design for the Royal Insurance Offices, Liverpool. No central feature is shown beyond the indication of a dome in outline.

The drawings are admirably rendered with much spirit, and the fine and vigorous sculpture is very pleasing.

The elevations have been projected, and must have given great trouble, though this is a dubious advantage.

No. 17 is the work of an architect who has made theatre design his own: a small block plan shows a quadrant upon the Strand front, with flanking towers on either side of a severe pediment, which in like manner are outflanked by towers of still greater altitude, which bring the public building to the avenues. Its architectural characteristic is confessedly un-Palladian, and would not be unsuitable for Chelsea flats on a large scale; it is treated with freedom but naturally suffers from the great repetition.

No. 27 is no doubt the work of the talented author of a delightful house at the corner of Palace Court, who evidently declines to be trammelled by severe limitations, and so we are presented with a vigorous conception, shown in a powerful and sketchable way. It is impossible, however, to view it as a whole, but rather as a collection of masterly sketches; in short, it is hardly serious. Looked at in part, there is much to interest; but we hope to be spared a go-ahead château in the Strand.

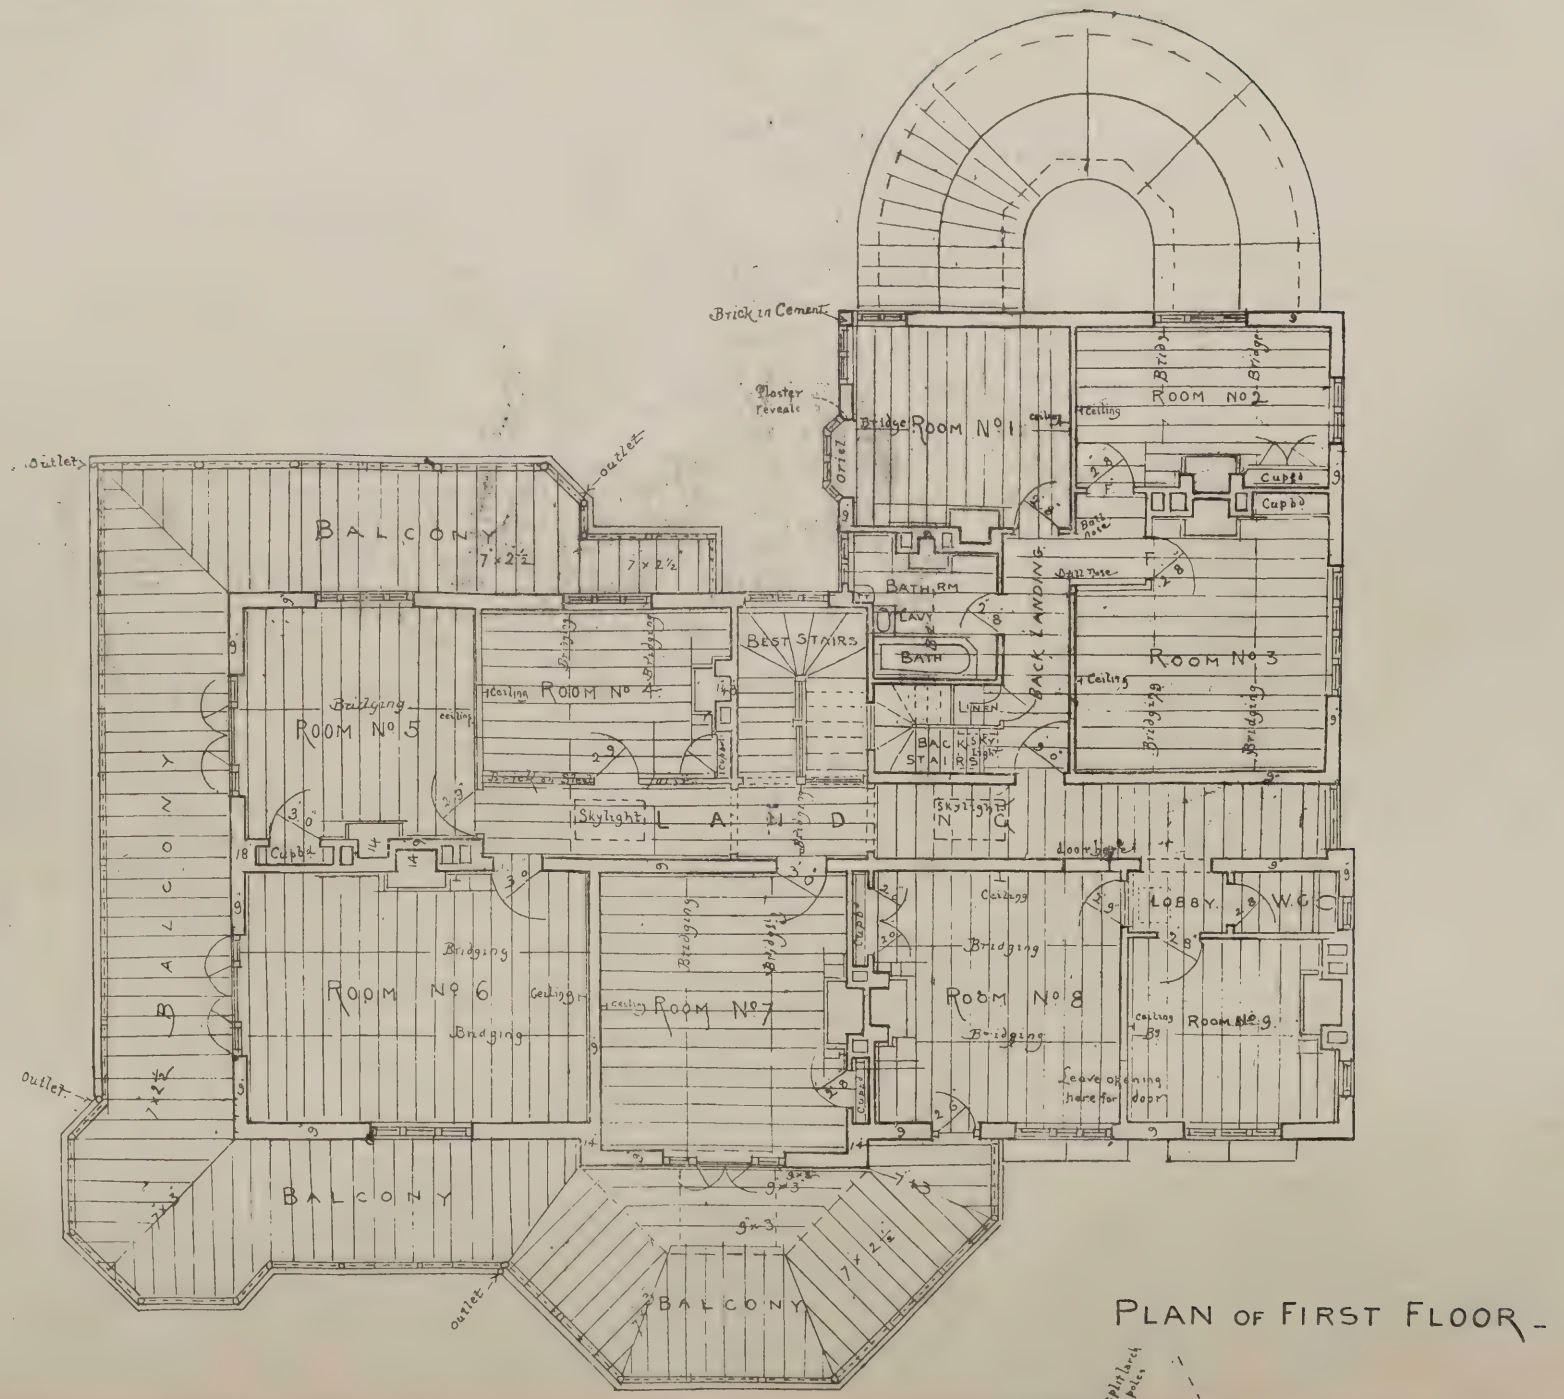
No. 20 submitted a fine monumental design some years ago for the South Kensington Museum, but that level has not been reached in the interesting collection here submitted.

The author has provided a more detailed plan than any other competitor, and is the only one who suggests a circus at the bottom of the new road, the centre of which is suggested as the site for a National Monument.

The character is generally Palladian; the County Building stands apart in theme and is somewhat underwindowed. These have pediments which run up to the frieze, the architrave being retained over the three-quarter columns. The drawings are carefully carried out, but in parts considerably overdone.

The names of the authors of the various designs are not yet made public, but we would say they are as follows:—No. 23, Mr. Ernest George; No. 26, Mr. H. T. Hare; No. 21, Mr. Reginald Blomfield; No. 19, Mr. E. W. Mountford; No. 29, Mr. Leonard Stokes; No. 17, Mr. Ernest Runtz; No. 27, Mr. William Flockhart; No. 20, Mr. Mervyn Macartney.

A new Technical Institute and Free Library at Tonbridge was opened recently.



Glasgow Institute of Architects.—The newly-elected council of this Institute held their first meeting last week, when the following office-bearers were elected:—President, Mr. John James Burnet, A.R.S.A.; vice-president, Mr. Alex. Petrie; auditor, Mr. W. Forrest Salmon; secretary and treasurer, Mr. C. J. MacLean, writer, 115 St. Vincent Street. The various committees for the year were appointed, including Committees on Architectural Education, Public Architecture, and Glasgow International Exhibition Architectural Photos Collection. The secretary reported that he had ascertained from the Corporation that the assessors appointed by this Institute to act with the city engineer in adjudicating on the designs sent in for the Cowcaddens and Woodside District Halls competition had duly issued their report, but that the Corporation had delayed the consideration of it meantime in view of the adoption of the Public Libraries Act, and the possibility of going forward with a new scheme for a combined public hall and library. The secretary was instructed to remind the Corporation that considerable hardship would be inflicted on the competitors if, in addition to the very long period of uncertainty and delay to which they had already been subjected, the scheme on which they had spent their labour on the understanding that the building as laid down in the published conditions was to be erected should be now altogether set aside; and to state further, that in the opinion of the Institute's council the competitor whose design in the first competition had been recommended for adoption by the assessors should be entrusted with the carrying out of the revised scheme without further competition.

New Patents.

These patents are open to opposition until December 3rd.

1899.—Brick Machines.—14,350. A. LOWE, Railway Cottage, Cowley Peachey, Uxbridge. By the combination of a moulding table, rising and falling moulds travelling in a circle, and pallet-board carriers, common sand stock bricks can be made in an ordinary pug mill with a considerable saving of labour.

Combination Ladders.—21,530. A. BARR, Campbell Cottage, Bothwell, Lanarkshire. This invention (which is an improvement on patent No. 24,183 of 1896) provides a structure which can be made into a ladder, an extensible ladder, a pair of steps, or a trestle. A swivelling catch is a leading feature.

Gullies.—23,064. J. PLACE AND SONS, LIMITED, Darwen, and W. H. PLACE, Darwen. The trap is placed outside the body of the gully (though integral with it) and the outlet is formed near the top, so that the capacity of the gully is not lessened by the trap being within it.

Window Sashes.—23,451. J. J. HARLEY, 27 Old Haymarket, Liverpool. Pieces of metal are fastened to the frame and to the sash in such a way that they are hidden when the sash is in position, and prevent the latter being opened beyond a certain limit. The invention has special reference to buildings in which persons are kept under restraint.

Light Metal Staircases.—23,510. E. WOOD & Co., LIMITED, Ordsal Lane, Manchester, and H. P. BUTLER, 107 New Park Road, Salford, Manchester. Metal stair-cases are usually of cast or wrought iron, and are necessarily heavy. The staircase which forms the subject of this invention is a very light one, having the treads made of thin steel pressed or stamped so as to provide a good foothold. Risers are also of light steel, and the whole is made secure with angle and other plates.

1900.—Chimney Tops.—848, J. LINKLETER, Tyneside Works, Tynemouth. The top is spiral in form, and is made from a metal disc of any desired size. This disc is cut spirally from the outer edge to the centre, and is then pulled out to the required length and fitted to a pot or tube.

Casement Holders.—14,672. G. F. DEAN, 6 Southey Road, Wimbledon. This holder is practically invisible. The arm is let into the window sill and the slot plate is secured to the underside of the casement. When the latter is opened the arm is automatically lifted clear of the holes in the slot plate and only drops into place when the opening movement is arrested.

The following specifications were published on Saturday last, and are open to opposition until December 10th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—17,588, LA SOC. ANON DES MANUFACTURES DES GLACES ET PRODUITS CHIMIQUES DE ST. GOBAIN CHAUNY ET CIREY, apparatus for polishing glass. 19,589, HUBBELL, vices. 20,346, VOELKER, manufacture of incandescent electric lamps. 20,877, IMPROVED ELECTRIC GLOW LAMP CO., LTD., & BARNES, manufacture of reflecting opalescent surfaces for electric lamps or glass reflectors. 21,710, WOOTTON, STALEY & PARKER, production of articles in clay. 22,828, ROSS, acetylene gas-generating apparatus. 22,957, BAKER, locks and fastenings for lavatories. 23,073, BAILEY & CLAPHAM, purification of acetylene gas. 23,474, STATTER & VAPOUR PREVENTER, LTD., apparatus for preventing or removing the deposit of moisture on shop windows and other cold surfaces. 23,545, BAILEY, mills or apparatus for grinding and polishing. 23,577, HEWITT, fireplaces or stoves. 23,612, LLOYD, water closets. 23,717, BAUMANN, grinding or crushing mills. 24,615, MILLS (*Pagnon*), process for mounting tiles. 25,716, DAVID KIMBERLEY AND SONS TOOL MANUFACTURING CO., LTD., AND KIMBERLEY, floor and other cramps.

1900.—9,275, PRIOR, process for hardening lime or calcareous sandstone for general building purposes. 9,782, CHISHOLM, manufacture of gas. 11,558, WURTS, systems of lighting by Nernst or similar electric lamps. 11,597, OSBURN, flexible conduits for electrical conductors. 11,638, GERMAINS, chimney cowl. 12,889, IBERT, steam pipe nozzles for heating water and other purposes. 12,938, LEGGE, door locks. 13,168, WARD, tar paving. 13,358, HECKEN, screwdriver with adjustable side claws. 13,366, OUSEY (*Globe-Wernicke Co.*), sliding doors for book and other cases. 13,369, OUSEY (*Globe-Wernicke Co.*), sliding doors, drawers, or slides for book and other cases. 13,425, SCHLOBACH AND WENTZLAU, fireplaces for promoting consumption of smoke. 13,848, WALSH, appliance for heating water by steam. 13,884, BURGUY, locks or latches. 14,295, BURGUY, locks for doors. 15,521, DAVIS, (*Hoskold*), theodolites.

Surveying and Sanitary Notes.

Street Improvements at Ince.—A Local Government Board enquiry was held recently into the application of the Council for sanction to borrow £2,350 for works of private street improvements.

A Dundee Street Improvement.—The Dundee Town Council propose to acquire from the railway company a strip of land which will allow of Drummond Street being widened, and Albany Terrace, or one of the parallel streets, continued through the gardens to Stirling Street.

The Sewerage Engineer's Note Book.—The St. Bride's Press, Ltd., 24 Bride Lane, Fleet Street, E.C., announce that on November 1st they will publish a second (revised) edition of Mr. Albert Wellheim's "The Sewerage Engineer's Note Book, being Standard Notes on Sewerage Formulæ and Sewerage Calculation." (Price 3s. 6d., post free.)

Crossbank Sewage Scheme.—The Rural District Council of Limehouse having applied to the Local Government Board for sanction to borrow £5,000 for purposes of sewerage and sewage disposal for the township of Crossbank, an enquiry was held by a Local Government Board inspector at Hey recently. The enquiry also concerned the propriety of constructing the sewage works within the urban district of Lees and an objection raised thereto.

Proposed Open Space at Hither Green.—The inhabitants of Hither Green, Lewisham, to the number of 1,000, have presented a petition to the Lewisham Board of Works, praying that body to preserve the estate known as "Mountsfield" as an open space. It is pointed out in the memorial that extensive building operations are being carried out at Hither Green, and that "Mountsfield" is at present for sale, and unless speedily bought by the local authority will be lost to the public.

Value of Land at West Ham.—At the Surveyors' Institution, Westminster, Mr. Alfred Savill sat as arbitrator in the case of "Smith *v.* The West Ham Corporation," to determine the value of 3a. 3r. 21p. of land at Silvertown, adjoining the Victoria Dock and the Victoria Graving Dock, which the Corporation have acquired for the erection of artisans' dwellings. Mr. Arthur Tapp, F.I.S., of the firm of Messrs. Tapp & Jones, surveyors, Princess Street, Westminster, said there was a great demand for house accommodation in the district, and the value of land had, during the last few years, largely increased and was still increasing. The piece of land was, until lately, used for grazing, at a rental of £13 per annum. His total valuation was £7,148, inclusive of 10 per cent. for compulsory sale. Eventually it was agreed to accept an award of £5,565, subject to the decision of the referee as to £120, the value of 20ft. of frontage in North Woolwich Road, the title of which was questioned. The amount was practically on the basis of £6 per foot frontage for North Woolwich Road, and £3 15s. per foot frontage in other adjacent roads.

OUR PLATES.

CLEVE COURT, STREATLEY, BERKS.

THIS house (by Messrs. Joseph Morris and Son, architects, of Reading) has been built for Sir William Ingram, Bart., upon a Thames-side meadow, over which water flowed to a depth of six feet during the high flood in the autumn of 1894. The floor of the house is one foot above that flood-level, so that the raising of the ground around the house required many thousand loads of chalk, which was brought in barges from Shooter's Hill at Pangbourne; when this supply failed the chalk was procured from the parish pit at Streatley: thus the bold enterprise and good taste of the owner have produced a charming garden out of what was, from its low level, a site most unlikely to be selected for building. The situation, however, is very charming, embracing delightful views of the river nooks of Cleeve Mill and the weirs, and commanding that lovely reach of the Thames from Cleeve Loch to Goring Bridge. To the south a full view of Streatley Hill is gained; and looking west the view is extensive over hills and wooded country. The house is approached from the Oxford Road by means of a long drive, which has been planted with lime trees and American shrubs, when the lodge gate is reached and the drive continues in a pleasing sweep, crossing a rustic bridge over the neck of the lake which has been formed for the double purpose of getting the effect of an irregular-shaped piece of water and affording the requisite soil for making up the lawns and gardens. A cut has been made from the Thames to the lake so as to form an approach to the picturesque thatched boathouse which has been built upon the shore of the lake. The house is planned with a view to future extension on the north side, which would lengthen the front facing the river. It is entered at the west side through a porch and vestibule into a square hall with ingle nook and bay window. From the hall a passage runs through the house to the garden entrance. The reception rooms face the south and east, and a wide verandah runs round three sides with balcony over. The bedrooms are partly in the roof, so as to keep the house as low as possible. The brick walls are of a subdued colour, and above them is half-timbered work, the panels being cream-coloured rough cast. The timbers are unwrought and stained a rich dark brown colour, contrasting pleasantly with the brick and rough cast. The windows and verandah are painted white.

The roof was intended to have been thatched; but the local sanitary authority who had to administer the Local Government Model By-laws were unable to allow this, so that brindled Broseley tiles were substituted; the "humped" dormers which had been prepared for thatch were retained, and the tiles carried over them, without breaking the courses, making a satisfactory finish both as regards appearance and weather-tightness. A terrace runs round the house with steps formed of larch poles in short lengths driven into the ground. The wings of the steps are formed with rockwork of Somersetshire spar. Throughout the architects have endeavoured to avoid as far as possible the usual formality of builder's work, and to give the house and its surroundings the effect of picturesqueness. The owner had some large willow trees removed from the ditch at the south boundary of his land: these were pollarded and replanted upon the lawns: by this and other devices the good taste of Sir William (in whom the architects found a client thoroughly appreciative of artistic possibilities) has overcome the difficulty of transforming a bare site into a fairly matured garden.

A new Duke's School for Alnwick is proposed to be erected by his Grace the Duke of Northumberland at a cost of £10,000, while the site is worth another £5,000. The site is twelve and a half acres in extent, and is very pleasantly situated on the south side of the town. While the new school is to be used for secondary and technical instruction, the old school will still continue as a useful elementary school.

Bricks and Mortar.

APHORISM FOR THE WEEK.

Ancient art is plastic; modern, pictorial.
SCHLEGEL.

Architectural Teaching in England. IN our issues for September 26th and October 3rd last attention was drawn to the fact that no Faculty of Architecture is provided in the University of London, and Mr. William Emerson's and Mr. T. Bailey Saunders' remarks on the subject in the "Times" were printed. Writing to the same newspaper, Mr. A. Robertson, Principal of King's College, says: "A department for the organised teaching of architecture in relation to applied science has for many years existed at this college. Within the last few years the teaching in this department has been developed into a systematic course of training which in thoroughness and efficiency is on a level with the existing schools of engineering in London. The course is of three years' duration. During those three years the student devotes his whole time to the college curriculum, beginning with mechanical and applied science, and specialising more exclusively in architecture in the latter part of the course. Owing to the exertions of the late Professor Fletcher, and to the generosity of the Carpenters' Company and other benefactors, the studio is equipped with an excellent collection of architectural casts; there is a very fine museum, containing specimens of materials, models, diagrams, and invaluable drawings in great number. There is also a special library. The department offers special facilities for the study of architecture, both as an art and as a branch of science. Whether the path to a degree in architecture is to be through the B.Sc. 'in engineering' with architecture as one of the alternative branches of study for that degree, or through a specially created degree in architecture *eo nomine*, is a question, involving debatable points of principle, which awaits the new Senate. But in either case the work of this college in the department of architecture is a fact to be taken into account. . . ."

The Opinions of Mr. Reginald Blomfield. IN reply to this, Mr. Reginald Blomfield says: "It is not necessary here to discuss the remarkable suggestion of the possibility of ranking architecture as a branch of engineering; what should be pointed out to the public, and more particularly to the new Senate, is that the whole idea of a degree in architecture is repugnant to a strong body of opinion in the profession itself, in regard to the fact that such a degree is about as practicable as a degree in painting or a degree in sculpture. The whole scheme of a degree in architecture is misleading to the public. All architects are agreed as to the necessity of an education in architecture as thorough as it is possible to provide, but practical men have bought their experience that this education must be something wider and more intimate than any that it is possible to provide in the class-room and the school. The provision for the technical education of architectural students in England is absurdly inadequate. If the few bodies that attempt this education were equipped and organised on the scale of the great German institutions, there would be something to be said for a method of training somewhat alien to English instincts."

Mr. Arthur Cates' Views. MR. ARTHUR CATES points out that the systematic course of architectural training indicated by Dr. Robertson appears to be rather a somewhat elementary course of engineering, specialising more exclusively in architecture in the third year, and not in any degree satisfying the requirements of a systematic course of teaching in the art and science, theory and practice of architecture, which alone would justify its claim to take its proper place in the studies of the university. A course of the description indicated cannot be accepted as affording a satisfactory systematic training in the study of architecture, or one at all comparable with the organised instruction available in France and Germany, or in any way approaching the admirable systems which within recent years have, under the influence of Professor William R. Ware, been established in the universities and colleges in the United States of America. . . . In these institutions a special matriculation examination must be passed to obtain admission to the classes. A satisfactory elementary knowledge of essential subjects is thus secured, and the training in architecture commences with the beginning of the course, is continuously developed throughout the whole period of teaching, and is not relegated to a mere specialising towards the end of the course. If Dr. Robertson and the Council of King's College, with the aid of Professor Elsey Smith, would carefully study the methods of the American Universities, which are so admirably adapted to meet the requirements of the case, and frame on a similar basis a systematic course of organised teaching of architecture, as an art and as a science, in both theory and practice, there might be some hope that when such a course was well established architecture might obtain that recognition from the London University which its importance to the nation, the State, and the individual demands for it, but which under existing conditions the Senate is hardly likely to extend to it."

Glasgow Exhibition Buildings. CONSIDERABLE progress has been made during the last few months with the Glasgow Exhibition buildings in the Kelvingrove Park, and the work has now reached a stage when some idea may be formed of the extent and design of the buildings. The Industrial Hall, the main portion of the Exhibition, is practically finished, with the exception of the great dome, and the contractors hope to complete it within the next few weeks, if given favourable weather. The flooring of the Industrial Hall is almost completed; the roofing and glazing are finished, and the plaster work has reached an advanced stage. With the erection of the great dome this part of the work will be quickly overtaken, as the material is already prepared, and the plasterers are ready to begin their labours when the framework of the dome has been erected. The various outside buildings, such as the dining halls, kiosks, &c., are beginning to take shape, and when the workmen now engaged in the Industrial Hall are turned on to these parts of the Exhibition their erection will be a matter of brief time. The Grand Concert Hall, to the north of the Industrial Hall, is also pretty well forward, the whole of the steelwork having been placed in position. Good progress is being made with the construction of the Grand Avenue, which connects the Industrial Hall with the Machinery Hall. Only a few yards of the arched woodwork require to be erected, and workmen are busily engaged roofing and plastering the rest. The bridge spanning Dumbarton Road, leading to the Machinery Hall, is expected to be out of the workmen's hands at an early date. The Machinery Hall itself is far advanced towards completion and is expected to be finished by the end of next month, and arrangements have been made to receive some of the exhibits about that time. There are 600 men at present employed in connection with the buildings, and the contractors are sanguine that the work will be finished in good time.

R.I.B.A. Kalendar. WE have received a copy of the Kalendar for 1900-1901 of the Royal Institute of British Architects, but there is nothing in it to specially note. The following is the programme for the forthcoming session:—November 5th, President's opening address; November 12th, Professor Lanciani on "Architectural Results of the Latest Excavations in the Forum;" December 3rd, business meeting; December 17th, Mr. Beresford Pite on "Some Tendencies of the Modern School of Architecture;" January 7th, 1901, business meeting; January 21st, award of prizes to students, with a paper on "Difficulties and Hindrances in Producing Good Modern Architecture," by Mr. J. J. Stevenson; February 4th, President's address to students and presentation of prizes; February 18th, Mr. G. T. Hine on "The Construction of Lunatic Asylums;" March 4th, business meeting (election of Royal Gold Medallist); March 18th, Mr. C. Harrison Townshend on "The Art of Pictorial Mosaic;" April 1st, Mr. Francis Bond on "The Classifications of Romanesque and Gothic Architecture; April 22nd, "The Work of Sir Charles Barry" (arranged by the Art Standing Committee); May 6th, annual general meeting; May 20th, Professor Flinders Petrie on "The Sources of Growth of Architecture in Egypt;" June 3rd, business meeting (annual elections); June 17th, presentation of the Royal Gold Medal.

London Bridge. THE proposal to widen London Bridge is still on foot and the Bridge House Estates Committee have many schemes under consideration. Mr. Ernest A. White, writing to the "City Press," points out very rightly that the Bridge is the most beautiful one spanning the Thames, and one of the best proportioned bridges in the world. It is simple, dignified, and monumental, and its gracefully turned arches thoroughly satisfy the eye, combining, as they do, lightness with strength. All that is required is extra width. "Surely," he says, "this could be effected without great difficulty or cost by removing the face on, say, the east side, and extending the bridge in width sufficiently to provide two more cartways, and additional width of footpath, refacing with the original masonry. Probably some property might have to be bought on each side of the river to achieve this, but the same would be necessary in building a new bridge, or in any way widening the present one. By this means one of the City's few beautiful buildings would be spared to us. People who condemn the bridge are those who attempt to judge it from what they see walking across each morning and evening. Needless to say, the design of a bridge can only be seen from the level of the river. To tamper with the design by removing the balustrade and bracketting out, a method I have seen suggested, would be an unwarrantable act of vandalism."

Burns's Cottage. Considerable alterations are being carried out at the birthplace of Robert Burns at Alloway. It is intended to remove a hall attached to the back of the cottage, used as a museum and temperance refreshment room, and to transfer the Burns relics from this to a new and larger hall in a range of cottage buildings which have just been completed within the grounds attached to the cottage. The caretaker and his family, who inhabit part of the cottage, have also been provided with accommodation in the new buildings. The cottage will thus be restored as far as possible to its original condition. The trustees, in resolving to make the alterations, were principally actuated by the desire to reduce the risk to the buildings from fire to a *minimum*, and with this end in view all fires and artificial lighting appliances will be removed, and the heating of the cottage will be from the hot-water system in the new buildings. A new turnstile will be put up opening into the grounds, which extend to seven acres, and access to the cottage will be from the grounds. The new buildings are ready for occupation, and it is intended that the alterations shall be completed during the present winter. It may be noted that when the new arrangements come into force no refreshments will be sold within the precincts.

Ancient Lights. AT the annual meeting of the Incorporated Law Society held at Weymouth on October 23rd, Mr. E. K. Blyth (London) discussed the question of ancient lights from the ethical and practical point of view. This rule of the law of England, resting upon statutory authority since 1832, did not exist, so far as he was aware, in any other country. It was the rule by which, if a man built a house with an aperture in the side wall overlooking the property of his neighbour, that aperture became in twenty years an "ancient light," and the ordinary legal right of the adjoining owner to build on his land or to heighten existing buildings was thereby curtailed. Mr. Blyth's examination of the subject led him to the following among other conclusions:—That the enactment of the Prescription

Act, 1832, by which a man may be partially deprived of the right to build on his own land by an act of his neighbour which he cannot prevent or restrain, and against which he can only protect himself by going to the waste expense of a retaliatory wall or blocking erection, was wrong, and ought to be repealed; and, further, that great practical injury arose from the present state of the law, especially in large and crowded cities, in which it interfered most seriously with the full user by landowners of their land in accordance with their proprietary rights, and the requirements of constantly growing commerce. He moved a resolution inviting the Council to take steps with a view to getting the law considered by the Legislature, and, if thought fit, to co-operate with the Royal Institute of British Architects and the Surveyors' Institution. This was seconded by Mr. Grantham Dodd and agreed to.

The Stage Carpenter. AT Paris M. Lugné-Poe, the founder of the Théâtre de l'Œuvre, is bewailing the incapacity of French stage carpenters, and making suggestions for the training and education of the body. They are neither born nor made, but drift into the profession by chance, and exercise it without intelligence or knowledge. It is to their ignorance and slavish adherence to stock rule-of-thumb methods and practices that the backward, embryonic state of French scenic art is to be ascribed. Anything in the nature of an innovation is regarded with horror by the stage carpenter, who esteems that rigid conservatism is the best cover for his utter incompetence. M. Lugné-Poe advocates the foundation of a technical school for stage carpenters, and hopes to obtain the support of the Paris Municipality for his project. The future craftsmen would be taught perspective and the elements of architecture, drawing, and mechanics. They would be instructed in scene shifting, and would study the properties of the materials employed in the construction of scenery. Some initiation into the principles of the art of decoration might complete the course, which would be followed by a period of apprenticeship in a theatre. It is certain that with master stage carpenters formed in this way to choose from, managers would only have to procure plays by geniuses, and clever actors, to realise the ideal theatre.

Cardiff Asylum Plans. AT a meeting of the Asylums Committee of the Cardiff Corporation held last week a letter from Dr. Stewart with reference to the new asylum plans was the special subject of consideration. Mr. Veall said that he had read the doctor's report, which had been drawn up (at request) after the plans and proposals had been considered. The doctor seemed to be opposed to a separate building for "acute" cases. The weight of experience and opinion amongst experts now was that asylums should be designed to deal with all classes of cases in one building. Mr. Veall suggested that the whole question should be referred to a sub-committee. The question raised by Dr. Stewart would have an important bearing upon the conditions under which the second stage of the competition upon the plans would be conducted. The committee decided to abandon the idea of a separate building, and the remainder of the questions were referred to a sub-committee.

Proposed new Law Courts for Leeds.—The Property Committee of the Leeds Corporation have unanimously confirmed the recommendation of the sub-committee to build separate law courts in the city and to adapt the Town Hall for municipal purposes. This decision will, in the ordinary course of procedure, be embodied in the minutes to be presented at the November meeting of the City Council; but in view of the heavy agenda on that occasion and the great importance of the subject, the members of the Corporation will be asked to postpone the consideration of the committee's recommendation to a subsequent meeting. The fact that the vote was a unanimous one will, no doubt, have considerable influence in the Council Chamber when the matter is discussed.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Welsh National Eisteddfod Competitions.

Referring to the query and answer about the above competitions given on page 230 of last week's issue, we have since learned that the hon. secretary for the next Eisteddfod is Mr. Sandford Jones, Merthyr Tydfil, from whom all particulars can be obtained.

Society of Architects' Examinations.

LONDON, S.E.—E. F. L. writes: "Are examinations still held by the Society of Architects, and if so, what is the date of the next?"

These examinations are held twice a year, in October and April. The October examination has just ended; the dates of the next examination (a syllabus of which will be sent on application) have been fixed for April 2nd, 3rd and 4th, 1901.

Cheap Wooden Casements.

LONDON.—CASEMENT writes: "Could you give me a rough sketch, plan and section for cheap wooden casements with rounded edges and no mouldings on transome or mullions and with plain oak sills? Would the rough sections sent herewith (not reproduced) answer the purpose for a house of cottage character covered with rough cast, no reveals to windows, but casement frames set back, say, 1in., with rough cast returned round window opening butting on casement frame, or with a small moulding to cover the joint where rough cast does not appear? How would casement fasteners be fastened to such casements, and would sections as shown be sufficient to keep out the weather?"

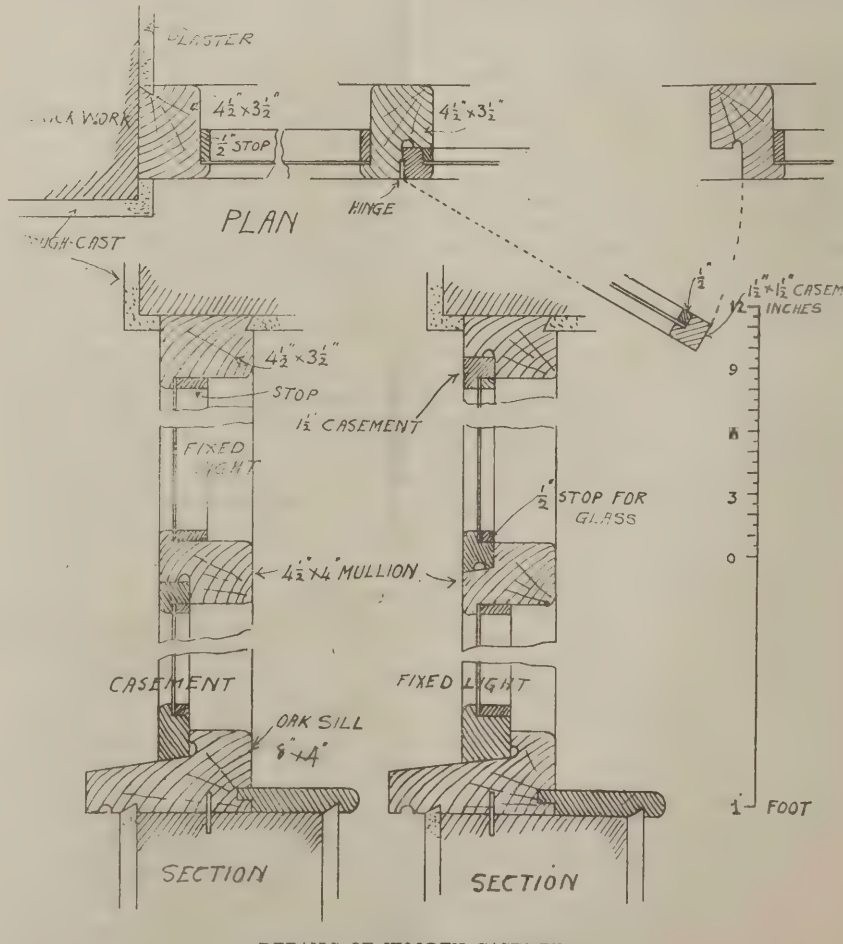
We think the accompanying sketches will suit the requirements. The glass should have a seating of chamois-leather or of vulcanite; the stops are easily removed for replacing broken panes with new glass—this is not the case with the sketch submitted by querist. The sections for keeping out rain were amply sufficient. We suggest that casement stays should be adopted in lieu of fasteners, the hinge of the arm being secured to the ½in. stop, and the pin and plate being fastened, in one case to the mullion, in the other to the sill, in such positions that with the pin through the first hole the casement would be locked shut.—R. W. C.

Stair Treads.

LEIGH.—ONE INTERESTED writes: "Is greenheart suitable for stair treads?"

There is one particular in which greenheart would answer well for stair treads—it is very hard, and therefore would wear well. For every other reason it is most unsuitable for the purpose; it is difficult to work, and the hard, close grain would cause it to wear almost as smooth as glass, and make it dangerous to walk up or down. I should therefore strongly advise querist not to use it for the purpose named.

TRAMMEL.



Iron Flue Divisions.

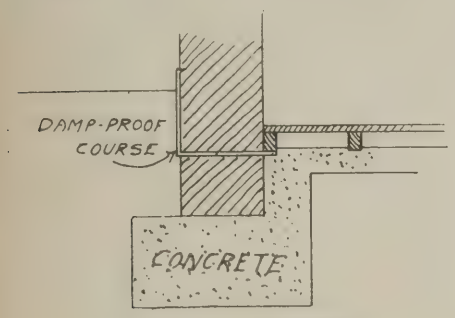
LARGS, N.B.—CLYDE writes: "Can you give us the name of the makers of a patent iron flue division for use when an air flue is next to a smoke flue?"

We have seen these iron flue divisions in many hospitals and other buildings; they are often called cast-iron withes. Those we saw last were made by Messrs. F. Newell & Co., of Stockwith-on-Trent, who would no doubt supply querist with full particulars of them.

Preventing a Draught in an Iron Church.

CHELTENHAM.—B. W. writes: "I am asked to prevent a draught in an iron church lined with matchboarding. Would any improvement be effected if the space between the iron and the boarding were filled with sawdust; also, if sawdust were used would there be any objectionable smell from elm and oak sawdust; or should deal and pine sawdust only be used? I might

DETAILS OF WOODEN CASEMENTS.



mention that felt was to have been put under the iron to keep out draught, but in many places this has not been done."

We do not at all recommend the use of sawdust for the purpose. The best means of stopping the draught would be to cover the outside of the matchboarding with Willesden paper of about two-ply thickness. This could be afterwards painted to an approved tint, and its use in this position would obviate the expense of stripping the boarding away and replacing.

R. W. C.

Damp Courses.

LONDON, S.W.—F. C. writes: "I am building a small house in the country and am in some doubt about the damp courses, as the ground is above the level of the floor and the intervening wall is not a hollow one. Would it be safe if I used slates set in cement horizontally just beneath the floor battens and vertically thence till the ground level is

DAMP-PROOF COURSES.

reached? I can use lead here as it happens, but would prefer to avoid asphalt."

We do not, of course, know what may be querist's objection to the use of asphalt, but we would strongly urge him to overcome it in this instance. If slates are used there will be an awkward joint at the junction of the vertical and horizontal portions, while asphalt could readily be worked in both positions and round the angle, and would adhere firmly to the walling. Lead could be used in the position indicated for asphalt, but slate should by no means be employed. (See accompanying sketch.)

R. W. C.

Law as to Water Chutes.

WICKHAM, HANTS.—A. B. writes: "My neighbour has forcibly removed my rainwater chute and thus cut off the supply of rainwater to an old tank in my garden. Has he power to do this, and is he open to prosecution?"

If the place where the old chute was forcibly removed is on your property, your neighbour would be liable to prosecution under the Malicious Damages Act, sec. 52, and also to compensate you for damage. If the place where the chute was removed was on your neighbour's property, your rights would depend upon the date and the terms of the sale to him of part of your garden. (See reply on page 93 of our issue for September 5th last.) A. O. H.

Professional Examinations.

NEWQUAY, CORNWALL. — PUPIL writes: "Which examination would you recommend a student to take up first, that of the Society of Architects or the Surveyors' Institution? I should like to go through both, but would prefer to take the easier one first. How long would it take to study the subject thoroughly?"

"Pupil" does not tell us what his previous training has been, nor which of the examinations held by the Surveyors' Institution he thinks of entering for. If he has had an architectural training, he should take the Society of Architects' examination first, but if his experience of architecture has only been slight he should sit for the S.I. exam. (that is, if it is the P.A.S.I. class he contemplates preparing for). The time required for study depends upon conditions which "Pupil" does not disclose. We should say a year, probably, but we know nothing of his present knowledge nor of his capacity for study, so that it might require much more time or much less.

R. W. C.

SOCIETY OF ARCHITECTS.

ANNUAL GENERAL MEETING.

THE annual general meeting of the Society of Architects was held on Thursday evening last at St. James's Hall, Piccadilly, W., when Mr. T. Walter Emden, L.C.C., presided. After the minutes of the last meeting had been read and confirmed Mr. Ellis Marsland read the report of the Council for the year ending October 31st last.

At the closing of the sixteenth session and of a somewhat eventful year of the Society's work, the Council are able to make a very satisfactory report of continued progress and increased activity. Since the resolution to double the annual subscription was confirmed, it is satisfactory to record that, with very few exceptions, the somewhat drastic but necessary step has met with approval, and has been the means of placing the Society in a position to carry on its work to much greater advantage, and to much increase its activity and influence.

Applications for membership continue to come in freely; the total number of members is now 569.

The Council regret the loss, by death, of seven members, including a distinguished hon. member, the late John Ruskin.

For the half-yearly examinations to qualify for membership held during April and October, some hundreds of enquiries were received, but the high standard maintained caused many to postpone sitting until better prepared. Four candidates sat, of whom one was successful.

While on the subject of education, the Council would call attention to the practical way in which the Society continues to uphold the compulsory education and registration of architects, by visiting the provinces and inviting discussion on this all-important subject. Four centres have been visited this session—namely, Exeter, Birmingham, Liverpool, and Manchester. Further meetings are only delayed by parliamentary and municipal elections.

Nine provincial meetings have now been held, at each of which a resolution in favour of the principle has been passed, interest in the subject has been stimulated, and mistaken ideas as to the attitude of the Society in the matter have been removed. It is now generally understood that while the Society does and will continue to do its utmost to carry into effect the measure introduced into Parliament by the Architects' Registration Bill Committee, they are quite prepared to co-operate with the R.I.B.A., if that body will take the lead and will give a definite pledge of their readiness to proceed with the work without delay. The Bill, which was down for second reading on June 15th last, was not reached owing to pressure of public business. A letter was sent to every member of the House of Commons asking for support, but the R.I.B.A. circularised the House in opposition to the measure, basing their objection to four of its clauses only, which could have been amended if Parliament thought right. Mr. L. A. Atherley Jones, Q.C., M.P., has charge of the measure, and members may be assured that no effort will be wanting on his part to secure another hearing for the Bill.

Reform in the law relating to Ancient Lights is another matter in which the Council have been moving for several years past, and they are pleased to find that their action in presenting a petition to the Lord Chancellor two years ago has been followed by the R.I.B.A. taking up the question, and the forming of a joint committee with the Surveyors' Institution to enquire into the present law with a view to its amendment.

It has for some time been felt that an improvement and enlargement of the Journal should be made, and it has been decided to commence a new volume in November, under the title of "The Architects' Magazine," which, while being as before the official organ of the Society, will also contain matter of general interest and information.

The success of the new venture will depend greatly upon the way in which it is taken up by the members, who, it is contemplated, are to be invited to contribute papers on special subjects, for which premiums will be warded.

The session having coincided with the opening and practical conclusion of military operations in South Africa, it may not be out of place to record that the Society has contributed both at home and in South Africa to the ranks of those who have volunteered for active service. Some of its members have taken part in the defence of Kimberley and the occupation of Johannesburg, while others have been cut off from the outer world at Bulawayo and other places. Members in China have also been passing through an anxious time.

A number of donations have been made to the library, and it is hoped shortly to render this most important adjunct more worthy of the Society by the formation of a library fund for the purchase of current publications.

The Register of Employment has not been made use of to the extent which was anticipated, and is one of those privileges of membership which is overlooked. It should be remembered that it is entirely free to members and students, and serves a most useful purpose as a medium of communication between employers and assistants; but so far it has been non-members of the Society who have mostly benefited by it.

With the view of impressing upon the Government the importance of issuing 6-inch colour-printed geological maps, the Council, by a memorial under seal, approached the Inter-Departmental Committee sitting to consider the progress of the geological survey. An encouraging reply from the chairman was received.

The telegrahic address "Crypt," has been registered, and will prove useful to members and others. The question of telephonic communication is also under consideration.

The Society of German Engineers having asked the Society to co-operate with them in preparing an international technical dictionary, the matter is having the attention of the Council.

The Society, in common with individual members of the profession, has had the claims of the Architects' Benevolent Society brought before them, and has become a subscriber. The Council would desire to remind members of the good which is being done by this, the only Society of the kind. The hon. secretary is Mr. Percevall Currey, 9 Conduit Street, W. The Council seeing that the possible effect of the passing into law of the Union of Benefices Bill might be the destruction of churches, resolved to oppose the Bill on these grounds. The Council have under consideration the question of issuing a form of building contract for the use of members and others, enquiries for such having been received from time to time.

It has been a source of much gratification to he Council that at their unanimous request the president (Mr. Emden) has allowed himself to be again nominated to the office, which he has so ably filled for the past three years.

In moving the adoption of the report Mr. Silvanus Trevail, F.R.I.B.A., expressed his gratification at the improvement which had been effected by increasing the annual subscription, and he was glad to say that less than 1 per cent. of the members had resigned on account of this step having been taken. He was sorry to see that the Royal Institute of British Architects still pursued their "dog-in-the-manger" policy in connection with Architect's Registration, especially in view of the fact that such registration was adopted in foreign countries and in our colonies. In concluding he paid a tribute to the indefatigable efforts of the president, Mr. Emden, and moved a vote of thanks for the valuable services which he had rendered to the Society. This was seconded by Mr. W. R. Mallett, and carried unanimously.

The following gentlemen were elected members:—Mr. Charles Carter (Nottingham), Mr. S. A. Gluckstein (London and Johannesburg), Mr. George Gush (Seaton, Devon), and Mr. J. F. Parker (London).

The officers and members of the Council for 1900–1901 were then elected as follows:—

President, Mr. T. Walter L. Emden, J.P., L.C.C.; Vice-Presidents, Lieut.-Col. F. Seymour Leslie, R.E., and Mr. Silvanus Trevail, F.R.I.B.A.; Honorary Secretary, Mr. Ellis Marsland; Honorary Corresponding Secretary, Mr. W.

Cooper; Honorary Treasurer, Mr. H. G. Quartermain; Honorary Auditor, Mr. J. R. Manning; Council: Messrs. James Bartlett, W. R. Bryden, F.R.I.B.A., Charles Caine, J. Williams Dunford, W. L. Grant, W. J. Jennings, W. R. Mallett, F.S.I., G. A. T. Middleton, A.R.I.B.A., A. E. Pridmore, J. H. Richardson, W. A. Scott, A.R.I.B.A., and W. W. Thomas.

Mr. Emden, in acknowledging the vote of thanks, said that he was glad to do all in his power for the Society, as he considered it to be the advance party in the architectural world, endeavouring to effect those changes which were for the benefit of the profession and the public at large. Votes of thanks were passed for the work done by the outgoing council and the meeting then terminated.

ARCHITECTURAL ASSOCIATION.

FRENCH AND ENGLISH CATHEDRALS.

By FRANCIS BOND, M.A., Hon. A.R.I.B.A.

A MEETING of this Association took place last Friday evening at No. 9 Conduit Street, Mr. W. H. Seth-Smith, president, in the chair. The minutes of the previous meeting having been read and confirmed, the following sixty gentlemen were elected members of the Association: Messrs. J. D. Robertson, W. A. Hodges, J. F. Schneider, D. W. Stewart, David Seth-Smith, H. Black, N. F. Barwell, T. R. Bridson, J. S. Brocklesby, J. O. Cook, I. S. Davies, W. W. Ellison, J. B. Fulton, G. Gould, R. H. Greig, H. C. Hollis, H. R. Houchin, J. R. Sykes, J. H. Waterworth, R. F. Wheatly, A. E. Bullock, P. R. Berry, G. Bune, H. W. Cathie, H. Colls, G. F. B. Dan'ell, C. René Harrison, D. B. Hedderwick, W. B. Hellard, F. Hibbard, D. M. Rees, W. A. S. Pettit, H. F. Murrell, A. F. Murray, H. S. Morran, H. Kenchington, W. B. Jemmett, D. B. Hart, R. G. Elwes, D. W. Crawford, A. S. Millar, C. S. Goodwin, G. Walker, L. Rawles, L. T. Moore, F. J. Sherrin, R. J. Howard, S. B. Wates, E. G. Theakston, R. E. Stewardson, I. T. Sifton, E. F. Reynolds, G. Unsworth, T. L. Walker, T. W. Watkins, H. J. Wyeth, A. E. R. Gill, A. B. D. Lang, A. E. Hyams, and H. Hyams. On the motion of the president a vote of thanks was accorded to Mr. G. B. Carvill, hon. secretary, for his services in connection with Association Conversazione held recently. Mr. Bond then read his paper on "French and English Cathedrals," as follows:—

An Englishman, just returned from a day trip to Boulogne, was asked what were his salient impressions of France. Two things, he said, filled him with astonishment. One was that the children in the streets spoke French; the other that the soldiers had red trousers and blue tunics, thus reversing the laws of nature. It is from this insular, and perhaps superficial, not from any cosmopolitan point of view, that I approach the subject of the French cathedrals; some of the French cathedrals, for there are a great many. It is possible to be on fairly intimate terms with all the English cathedrals, of which there are no more than thirty-four, even including those churches which have been elevated to the rank of cathedrals in the present reign. In France, on the other hand, it is impossible to be even on bowing terms with the churches which are at present, or which have been, of cathedral rank. The south-east of France swarms with little cathedrals; even their names will be unfamiliar to many, such as Castres, Cavaillon, Dax. I have even had to explain sometimes where Séez is. Obviously, our survey must be limited to but a few of this vast number.

Let us look in imagination, first at the English cathedrals, and secondly at the more important of their sisters in France. I think I may take it that anyone who has visited and studied our

English Cathedrals

does not afterwards mix them up in his memory; he can always keep each picture distinct; that is, the English cathedrals have the quality of distinction and individuality. For example, we never confuse with one another designs, though on closely analogous lines, such as those of the choirs of Beverley, Lincoln, Ely, Southwell, Worcester, and Salisbury. In the same way the *tout ensemble* of the interior of Ely stands out apart sharply and clearly from that of the interior of Lincoln or Gloucester, or York. Yet more individual are the exteriors. Exeter reminds us of nothing else; nor does Lincoln or Lichfield, or Canterbury, or Wells. Now this is by no means the case in France; or at any rate, not to the same extent. In the two interiors, one of the choir of Amiens, the other the nave of Auxerre, the differences between the two designs are so slight, that, without care and thought, it is really difficult to remember which is which. And this is so with a great number of churches in

The Style of the Ile de France.

Three years ago I spent a month among them; and I must confess to finding them somewhat monotonous and uninteresting. The fact is they were all to a large extent versions of Amiens. In Amiens every problem of French Gothic had been solved consummately. In no way could Amiens be bettered; and so this—the greatest of all the great works of the French Gothic—inspired, dictated, and controlled the great mass of Gothic design even to the furthest ends of the country. So, when I reached St. Quentin, Chalons-sur-Marne, Troyes, Nevers, Auxerre, Tours, Rouen, Clermont-Ferraud, Limoges, Toulouse, Narbonne, I was constantly finding myself in the presence of something which I had seen before. Evidently, about 1220, the thought of the best builders throughout Northern France flowed in the direction of the Amiens design; and the ideas which produced Amiens produced, or were soon to produce, similar work throughout the length and breadth of the country. In England, fortunately or unfortunately, we never had an Amiens. We never had one final summing up in one building of the best in our English Gothic. Wells choir had been an enormous advance about 1175. St. Hugh's design at Lincoln fifteen years later, though he came from Witham, near Wells is in no way based on that of Wells. His choir, in turn, was a vast advance, yet no copy was made of it. There was never in England a superior person like Amiens to set the fashion. Not only English Gothic was non-French, but cathedral after cathedral went on its own sweet way, copying nobody. For that very reason, small as many of our cathedrals are, they are for their number—at any rate, as far as my opinion goes—more interesting than the cathedrals of the style of the Ile de France.

On the other hand, we must admit that there are French cathedrals which have enormous individuality. Nothing was built like Chatres before it; nothing has been built like it since. Rheims, too, stands out alone. Then there is a group of three cathedrals with double aisles of unequal height; Bourges was built first, being commenced about 1190; Beauvais and Le Mans were improved versions of Bourges. Le Mans, had it been completed, would, I think, have eclipsed even Amiens. Then there is a fine group of Transitional Churches which have marked individuality—Paris, Sens, Senlis, Noyon, Soissons, and Laon; to which we may add the noble choirs of St. Remi and Notre Dame of Chalons-sur-Marne. Travel yet farther from Paris, and new and strange, yet beautiful, varieties of Gothic will be found. The lovely "Norman patois" is seen in the choirs of the Abbaye-aux-hommes and Bayeux; at Séez and Coutances; delightful links between the Ile de France and England. Travel far west; and in the choir of the Cathedral of Chalons-sur-Saône, at Sémur and Notre Dame de Cluny will be found another Gothic, bold, vigorous, and independent. Nor will the achievements of what the French call

Plantagenet Gothic,

designs wrought in English realms, not by English brains, ever fail to leave sharp and distinct recollections of lovely work, from St. Serge at Angers to the magnificent cathedral of Poitiers, commenced about the year 1162 by our English Queen Eleanor. Going down south, an Englishman finds himself confronted more and more with churches strange, novel, and interesting. Some of them, like Toulouse and Bordeaux, have an aisled choir and an aisleless nave—a combination magnificently successful at Bordeaux. At last, at Albi, aisles disappear altogether; the whole cathedral becomes one continuous hall; stupendously impressive. If there is monotony in the Gothic of the Ile de France, there is none when its limits have been crossed. There is absolutely nothing in English Gothic to parallel these immense differences of French design. To the faithful who have learnt their Amiens, Poitiers and Albi are a bolt from the blue.

Another important difference is that the French cathedral in those districts which the tourist is most likely to visit is

Wholly Gothic.

The exceptions are very few. At Nevers a western apse of the eleventh century survives, in striking contact with a thirteenth century Gothic cathedral. At Beauvais the fall of the central spire preserved from rebuilding an archaic nave of the tenth or eleventh century and Romanesque sub-structures remain at Bayeux and Chalons-sur-Sâone. But out of our thirty-four English cathedrals, Peterborough and Durham are still mainly Romanesque; while large masses of Romanesque work remain incorporated in Bristol, Canterbury, Carlisle, Chester, Chichester, Ely, Exeter, Gloucester, Hereford, Lincoln, Norwich, Oxford, Ripon, Rochester, St. Albans, Southwell, Winchester, and Worcester. So that of our older cathedrals only Lichfield, Salisbury, Wells, and York are purely Gothic buildings. An extraordinarily clean sweep was made in the thirteenth century of what Romanesque there was in the Domaine Royale; and its corresponding abundance in the English cathedrals forms one of the most striking points of difference between the mediæval architecture of the two countries.

If we look at the two sets of cathedrals chronologically we shall find equally marked differences. In England each period is fully represented by important cathedral work. In France it is not so. The period of Transitional or Rudimentary Gothic is well represented in England at Oxford, Ripon, Canterbury, and Chichester; in France, by the cathedrals of Paris, Laon, Sens, Soissons, Noyon, Senlis, and to some extent by Chartres. Our lancet and geometrical work is represented by the great group of Gothic cathedrals of the Ile de France type. Our Tudor work ran on simultaneously with

The French Flamboyant.

In the preceding period much grand work was done at Bristol, Carlisle, Chester, Ely, Lichfield, Lincoln, Oxford, St. Albans, Wells, Worcester, Gloucester, Canterbury, and York. In many parts of France work stops almost wholly from about 1328 to 1440, when the French were engaged in the most calamitous intestine conflicts, and for a hundred years were at war with ourselves. This period of anarchy, warfare, famine, and plague was no fit seed ground for architecture. The tale of those days is told quite clearly in many a French cathedral. You see quite distinctly where the works were suddenly stopped in the fourteenth century. You see where they were resumed late in the fifteenth century. When they were resumed, however, a great change had come over the spirit of Gothic architecture. In the natural course of things the choir, with some exceptions, for instance Amiens, had been built first. Then the nave was completed. (At Clermont, Limoges, and Moulins the naves were only finished in the present century, that of Narbonne still remains a skeleton.) As a rule, it was just when nave and choir had been finished that war, civil and foreign, stopped the work. In most cases the transepts had been left to complete later; and so it is that we have the constant juxtaposition in a French cathedral of an Early Gothic nave and choir with a Flamboyant transept. In fact, this may be regarded as the

Normal Type

of a French Gothic cathedral. It is seen at Paris, Sens, St. Remi, Amiens, Limoges, Beauvais, Auxerre, Troyes, Senlis, Séez. Very magnificent these Flamboyant transepts are. Whatever be the failings of Late Gothic, we cannot afford to despise the composition of such transepts as those of Beauvais and Limoges, any more than that of such spires of our own as Coventry and Louth, of equally late date.

Externally the French cathedral is, above all, a town church. It rises out of the huxtering of the *place* or the squalor of the narrow lane. In front perhaps is a Sahara of dust, as at Amiens, Auxerre, Paris, Rouen. From no point of view can the grouping of the whole of its masses be seen. Nowhere in France is there such a comprehensive view as that from the north-east of Salisbury or Lincoln. It is seen only in parcels. Sens, for example, has an arid space in front; to the north it is blocked by private houses; to the south by the Archbishop's palace; to the east by the Grande Séminaire. Peeps and glimpses only can be got of transepts, choir, nave, and apse. A general view is impossible.

It is a surprise to see the south side of Bourges rising out of the emerald sward. The peaceful close and elms of Salisbury, the pools and springs of Lichfield and Wells, the wooded slopes and river of Durham, the encircling precincts of ancient canons' houses embowered in foliage and creepers, are all wanting in France.

In France we see the Bare Picture;

in England we see it framed. In England such cathedrals as Canterbury, Durham, Ely, Lichfield, Lincoln, St. Albans, Wells, York, nobly dominate the town and landscape. With us the houses are low, and give the cathedral value; in France they are much loftier, and strangle the great building in their close confines. Indeed, the real greatness of the building is often quite unrecognisable from outside. Mr. Garbett, in his "Principles of Design," quotes an eminent authority who honestly thought Salisbury larger than Amiens. His error was pardonable. Following the south side of Amiens, one sees three things only—the nave, the transept, and the apsidal choir. Following the north side of Salisbury, one sees nave, porch, nave, great transept, choir, eastern transept, choir, retro-choir, Lady Chapel. This bold handling of the masses infinitely increases the apparent magnitude of an English cathedral; nor must one forget the gulfs and abysses of shadow in the deeply-recessed flanks of such cathedrals as Lincoln and Salisbury, to which it gives rise. Especially is this the case where the plan with double transepts has been adopted. It is a strange fact that this, the archiepiscopal plan, appeared first in France; at Cluny and its daughter abbey, Souvigny. It found no favour in its own country, but its adoption in England gave us the finest exteriors we possess.

A French cathedral is essentially a

Town Church;

the English cathedral dwelt in a *rus in urbe*. To these delightful closes and precincts yet another charm is added in their cloisters. Cloisters were natural in cathedrals which, like Gloucester or Bristol, were served by Benedictine monks or by Augustinian canons. So beautiful an accessory, however, was the monastic cloister that it was added as an *objet de luxe* at Chichester, Exeter, Hereford, Lincoln, Salisbury, and Wells; all served by secular canons. In Northern France, on the other hand, cathedral cloisters are far less common. Among better known examples may be mentioned those of Rouen, Laon, Noyon. In England, too, we elaborated first at Worcester a circular chapter-house, and out of this developed the polygonal form. These polygonal chapter-houses, of which so many glorious examples remain, e.g., at Southwell and Wells, have been described as the greatest triumphs of our mediæval architecture. I do not remember to have seen one of them in France.

Where the exterior can be seen, it is seen to be

Hugely Tall;

its outlines, however, especially as one looks eastward towards the apse, are cut up in the most perplexing and vexatious manner by a forest of stone stays—permanent stone scaffolding—the flying buttresses. One's reason tells one that each has its special function, but the eye does not brook to be dictated to by the reason. After the tangled intricacies of such an apse as that of Amiens or Nevers, the eye rests with deep content on the simplicity of the north side of York.

We have seen how porch and eastern transept break up the monotony of the long flanks of our English cathedrals. The French cathedral also, as first designed, had grand shadow effects in the bays between the buttresses; buttresses which, owing to the greater height and span of the vaults within, were of much greater projection than our own. Unfortunately these effects, too, were sacrificed almost everywhere.

The Walls of the Nave Aisles

were pierced through, and chapels were inserted from buttress to buttress. The buttresses practically disappeared as a factor of the exterior; and the flanks of the nave presented one shadowless monotony. This may be seen at Paris, Laon, Nevers, Dreux, Amiens, Autun, almost everywhere. We have had but one nave treated in this disastrous fashion; that of Chichester.

Another disability which afflicted the French designer was that the interior being all in all to him, and the sublimity of the interior being dependent mainly on its altitude, the external roof which covered his vault was so enormously lofty that no towers which could be set upon it were adequate to dominate its masses, unless they were positively gigantic in height. It was only by carrying up spires to the vast altitudes of those of Cologne or Strasbourg that such an exterior could be brought together into unity. In some cases, as at Chartres and Coutances, the attempt was made, and successfully. At Beauvais it was attempted; but the central spire, 510ft. high, collapsed. At Amiens, the *chef d'œuvre* of all the French cathedrals, the

Failure of the Exterior

is supreme. Over the crossing was erected a spire of wood; though 357ft. high, it has the effect merely of a pinnacle. As for the western towers of Amiens, though effective from the west, they are from all other points of view absurdly inadequate. In England, vaulting ambition did not overleap itself.

The Lincoln people kept their roof so low that the three towers have a superb effect. What must Lincoln have been like when it had its three spires as well? the central spire, 525ft. high, a mark far out at sea!

Not only in the elevation of his vaults, but in the composition of his tower-groups, the Frenchman had ambitions amazing to the Englishman. The Englishman never got further than translating into Gothic the Abbaye aux Hommes. The Frenchman essayed to translate into Gothic the tower-groups of Cluny. Laon was designed for seven towers, Chartres for eight. No such groups were ever completed. And so French Gothic is, to a woeful extent, a study of

Unfinished Exteriors—

unfinished where groups had been designed of seven, eight, or nine towers; unfinished often where, as at Amiens, three steeples only had been planned. We see something of what was designed in the tower-groups of Laon, and in a simpler form at Autun, Semur, and Notre Dame de l'Epine, Chalons; or, with intermixtures of modern work, in the Cathedral and St. Ouen, Rouen, in Bayeux, and, above all, in Coutances, the finest tower-group in France. Taking the French exteriors as a whole, one is left rather well content with English Gothic.

But if we turn to the grand façades to north, south, and west we have little, I am afraid, which will bear comparison. A few of our transept-façades, e.g., those of Beverley and Lincoln and the north transept of York, have no superiors anywhere. (It is strange that we have no façade of first rank after the middle of the thirteenth century.) As has been pointed out, the final and most elaborate effort of French Gothic was made in the

Completion of Transepts.

What can be more accomplished than the composition of the north transept of Limoges? How commonplace it would have been in the hands of our contemporary English masons! If, on the other hand, we turn to the west, the French façade immeasurably surpasses anything of ours, Peterborough excepted, which is *hors concours*, being unique. In France they wanted to display statuary, but the grand façade does not sink to the level of an open-air reredos, as at Lincoln, Salisbury, and Wells. Nor can I conceive any French architect so lost to dignity and self-respect as to let his cathedral sink away westward to the ground after the parochial fashion of Winchester, Norwich, Chester, Gloucester, and Worcester. Sometimes, but rarely, he built two symmetrical spires, as at Séez, Angers, Bayeux, Coutances; or two unsymmetrical ones, as at Chartres. Sometimes he built a pair of western towers, as at Paris, Rheims, Bourges, Noyon, Tours, Laon. It is possible that these also were intended to carry spires. (The addition of spires is needed to counterbalance the heaviness and undue horizontality of the present façade of Notre Dame, Paris.) If he could not complete two western towers, at any rate he built one, as at Auxerre, Soissons, Limoges, Troyes, Albi. If he did not get his tower at the west, then, as at Exeter, it finds place at the end of the transept, e.g., at Bordeaux, Le Mans, Nevers. Of our west fronts, that of York is most on French lines and the most successful, always excepting Peterborough. The evolution of the

French Grand Façade

from Senlis through Nôtre Dame to its perfect consummation in Rheims is a fascinating subject which I must pass over.

In such a great façade the central idea is that it is none other than the portal of the House of God Himself. Here there are none of those "holes for rats and mice," as some one unkindly described the west doorways of Wells. These vast cavernous portals, studded with legendary imagery, are the glory of the French façade. The triple portals of Paris, Auxerre, Amiens, Rheims, will be familiar to many of you; while at Bourges the western entrances are no less than five in number. It is true that the comparative insignificance of the

Western Entrances

to our cathedrals is to some extent redeemed by lateral porches breaking most effectively the lines of our long low minsters, such as the north porches of Southwell, Hereford, Salisbury, Wells, and Worcester; the south porch of Canterbury; and the Galilee porches of Ely and Lincoln. But France also has noble examples of lateral porches—the lovely hawthorn porch of Bourges; the statued porches of Chartres; and the superb Flamboyant porches added to Louviers and Albi, the latter incomparable among the works of the Later Gothic. On the whole, as regards the façades of naves and transepts alike, we must bow to the superiority of the French.

When we pass within, all is changed. We step into vast spaces of height incalculable; so overwhelming in their impression on the senses that it seems inconceivable that they should have been designed by the pigmy, man, who walks beneath. Nowhere does one so feel at once the insignificance and the greatness of man; he is overwhelmed by his own work. It is not to the beautiful but to

The Sublime

that the genius of France has attained. Her Gothic cathedrals stand apart on a higher plane than all the other works of man; they are the supreme artistic achievement of our race. At Lincoln the choir is 74ft. high beneath the vault; at Amiens it is 140ft.; Beauvais is nearly 154ft. (one Lincoln choir might well be superposed on another inside Beauvais). It is true that our English cathedrals have the best of it in length. Winchester is 56ft. longer than Amiens, and very beautiful effects are produced by the long-drawn succession of arch after arch rapidly passing out of count. In fact, we may say Frenchmen and Englishmen alike, in building a house for Him who is without length of days, sought to produce the impression of infinity—in England by suggesting infinite length, in France by suggesting infinite height. Ours was the easier task. And this impression of interminable distance was aided yet again by the numerous screens, often carrying organs, which crossed the church; of which two remain at Ottery St. Mary's, while greater churches had three or more. How greatly an interior is foreshortened by the

Want of a Substantial Screen

is seen at Tewkesbury. At Gloucester and at Exeter the organ-bearing screens add enormously to the apparent length of the church. Screens have been swept away from the French cathedrals almost universally. Their length,

already inadequate to our English eyes in proportion to the greater span and greater height of the central nave, is grievously curtailed. A beautiful example remains at Notre Dame de l'Epine, near Chalons-sur-Marne. A sumptuous Flamboyant screen is the glory of the church of the Madeleine at Troyes. The Renaissance screen of Limoges Cathedral still survives, but is thrust back against the western wall. Albi alone retains in all its integrity the whole of its screen and choir enclosure.

What, perhaps, strikes an Englishman most is the homogeneity of the whole

Internal Design of Nave and Choir.

He has been accustomed to nothing of this, except, perchance, at Salisbury. To him a cathedral means a hybrid, a mongrel building—a collection of scraps and patches. It is a revelation to see a harmonious whole, like that of Paris or Amiens or Bourges or Rheims or Chartres or Poitiers, Laon, Soissons, Noyon, Tours, Troyes, Coutances, Séez. At Chichester, for instance, he has seen one design in the nave, a second in the retro-choir, a third in the porches, several designs in the nave chapels, one in the south transept, and another in the north. Equally mixed up and discordant are Rochester, Hereford, and St. Albans. York has one design for the transept, another for the nave and choir. Canterbury choir is absolutely disconnected from and independent of nave and transepts, and so on with the rest, Salisbury only excepted. This, which is the

Greatest Blot Æsthetically

in our English cathedrals, is archæologically their greatest charm. When one has seen one bay of the nave of Salisbury or Amiens, one knows what to expect in each of the rest; there are to be no surprises, no novelties. In such a cathedral, too, as Amiens or Salisbury there are few archæological problems to unravel, few nuts to crack; the constructional history of the cathedral tells itself clearly and unmistakably. But a man must think much and often, and even then he will require Mr. St. John Hope's assistance, to ascertain how Rochester Cathedral grew. I remember finding Wakefield and Ripon Cathedrals more interesting than stately York. Here and there, like the Frenchmen, we were iconoclasts. At Lichfield, Salisbury, Wells, and York the builders cleared away every scrap of Romanesque from the face of the earth. But everywhere else they left masses of Romanesque work standing. Often we have a Romanesque nave with a Gothic choir, as at Southwell; sometimes Romanesque below and Gothic above, as in the choir of Hereford; sometimes blocks of gaunt Romanesque protruding still from Gothic surroundings, as at St. Albans. Parallels may be found in France, but they are rare. Toulouse has a Gothic choir, but never succeeded in rebuilding its twelfth-century hall nave. The Romanesque nave of Le Mans was thought too good to be pulled down. Gothic is superposed on Romanesque at Bayeux, at Chalons-sur-Saône, and at the abbeys of Souvigny and Brioude. But, on the whole, we may say that English cathedral architecture is generally a study of contrasts; that of France a

Study of Harmonies.

If we turn to the internal elevation we shall find a marked difference between the French and the English treatment. The English cathedrals are low; the loftiest vaulted cathedral, Salisbury, is 85ft. high. They sink downward till 74ft. is reached in Lincoln choir, and 70ft. in Exeter. This conditions the English elevation. For an effective interior the piers and pier arches must be lofty. But where the vaults are low there is no room for lofty piers and arches. The piers have to be short and squat, as at Wells and Lichfield. What a change to turn from these to the acute, soaring arches of Amiens, Clermont, and Narbonne! Both in France and England the internal elevation usually consists of three members—the pier arcade, triforium, and clerestory. The French disposition of these—which is seen at Westminster and Beverley—is to give half the height to the pier arcade, and of the other half to assign one-third to the triforium and two-thirds to the clerestory. Some such proportions prevail almost everywhere in France. In England the proportions are seldom good. The clerestory, as a rule, is too low and the triforium too lofty.

The greatest difference, however, as regards proportion is the

Relation of Height to Span.

With us, except at Westminster, Norwich, and Beverley, the height is usually only about twice the span. In France, though the central aisles are much wider than our own, they are usually three times as high as they are broad. It is beyond question that in the matter of proportion English Gothic erred; and proportion, as some one has said, is the life-blood of architecture.

As I have said, we were often inclined to sacrifice the clerestory to the triforium. The fact is, there was in England a very genuine love for the triforium, and a great and well-founded belief in its capacities for artistic development. The French, I think, at no time set much store by it. In great churches, such as Chartres, Limoges, and the choir of Auxerre, the triforium is of a very simple character. Our rich triforia, such as those of Chichester retro-choir, Lichfield, Lincoln, Salisbury, Worcester, Westminster, Beverley, and York, are the exception in France. The elaborate triforium of Séez is one of the proofs of the presence of English influence in the design of that beautiful little cathedral; and when it does occur it is seldom a blind storey proper. As a rule, as in Amiens nave, it is blocked up behind by a solid wall. In this way the Frenchman deliberately gets rid of

The Pits of Shadow and Gloom

which lie at the back of the arcades of such an open triforium as that of Lincoln presbytery. Frequently, after the middle of the thirteenth century, he lowers the aisle roofs and glazes his triforium, as in Amiens choir, Clermont-Ferrand, and St. Ouen, Rouen. But this is no gain. The clear-storey at Clermont-Ferrand is quite tall enough without having a triforium added to it. One instinctively desiderates a three-storey elevation; the Frenchman has reduced it to an elevation of two storeys. In twelfth-century Gothic an elevation of four storeys had not been uncommon. It is seen at Laon, Soissons, and Noyon, and survives in part in Paris. It is seen in transition in Rouen Cathedral and in the fine church of Eu. The extra storey is gained by vaulting the aisle in two storeys instead of one. The additional storey has the effect of increasing the apparent height of the church. The objection to it was that it curtailed the pier arcade and clearstory.

Looking east or west, unity is the mark of the French design. The French cathedral is a house at one with itself. This is largely due to the absence of a central tower and of the obstructive piers on which such a tower rests.

Our Exteriors

owe much to the central towers; our interiors are ruined by them. Canterbury nave and choir are as much disconnected as if they were in separate counties; it is not one but two Canterbury Cathedrals. It is rarely so in Northern France, except in Normandy and Burgundy. The beautiful church of Sémur is constricted into a mere tunnel, in order to allow of a stone central spire. At Bourges, at Bazas, and Nevers even the transept is omitted; at Albi the aisles were omitted as well. Nothing was allowed to stop the uninterrupted flow of the main lines of the church from west to east.

In plan the French cathedral attaches more closely to the type of Hereford, Exeter, Winchester, Salisbury, and Wells than to the simple parallelograms of Lincoln and York. It is, indeed, from the east end of Wells only that we can form any conception of the mysterious, intricate, everchanging vistas and perspectives which fascinate one in a French chevet. The eastern glass walls of Lincoln and York are plain prose indeed to

The Poetry of the Eastern Endings

of the French cathedrals. And when it is remembered that some of the French cathedrals have double aisles to their nave, and that nearly all have their aisles flanked by continuous chapels, it will be seen that there is a romance about the progress up a French cathedral from portal to altar which is here unknown. If, however, we have not the seven chapels of the chevet of Amiens, the eleven of Orleans, the seven of Le Mans, we have by compensation the eastern transept—a most picturesque substitute. And while we are speaking of transepts, it is worth noting that the English transept has usually an aisle on the eastern side only, on which side alone altared chapels were practicable. Beverley and Salisbury are examples. Even in religious art the Englishman was ever practical and economical. I do not recollect these lopsided transepts in France.

As regards detail, I think we may say that the Englishman sometimes bestowed on his detail a loving care which is not always found on the other side of the Channel.

The Frenchman's Mouldings

are few and bold. The outline of the pier arches is not marked, as with us, by an emphatic hood-mould. His piers, on plan, are simple in comparison with those of Wells, Lichfield, and Exeter. But the Englishman as soon as he had begun to learn the new lesson of Gothic burst at once into an intricacy of delicate, refined mouldings such as the Frenchmen never dreamed of. Take a first-class example from either country—the cloister of Mount St. Michel and the Beverley staircase—and you will see the difference. In statuary our case is hopeless. I know of nothing to compare with the statue of the Virgin in the group of the Annunciation, which stands in the central doorway of the façade of Rheims. In foliated capitals nothing, perhaps, was ever done so good as the twelfth-century capitals of Sens, Laon, Soissons—truly architectural in treatment. In later days marvels of foliage were produced—conventional foliage of the highest beauty at Wells and Lichfield; naturalistic work in the Chapter House of Southwell. With the latter we may compare the fine capitals of Notre Dame, Cluny, and the superb example from the nave of Rheims. Honours may be said to be divided.

"It is not so above." Look at the vault, What a poor, thin, ineffective culmination and climax for the riches below! Think of the vaults of the naves of Lincoln and Lichfield, of Norwich, Tewkesbury, and Winchester, and, above all, of that of Exeter, fastening down and tying the whole building together, like the banded lid of some ancient strong-box. Particularly lamentable is the absence in France of

The Longitudinal Ridge-rib.

More than anything else this binds together a cathedral's disconnected bays and enforces unity. Examples of it do occur, e.g., at Souvigny and St. Riquier, but they are rare. The reason, I think, is not far to seek. The French, to lessen the thrusts, always inclined to build their vaults domical. Introduce a ridge-rib and it will be found to wobble up and down in a most distressful manner, as, indeed, it does in the great transept of Lincoln and in Southwell choir. Only at the very end, when it was too late, did the French repent, as at Abbeville and St. Riquier, of their failure to develop the vault.

And so we get back to our normal attitude of complacency. We do not get the "grand Nature" in our English cathedrals. They are human and lovable; foreign travel does not spoil one for them; one ever comes back to the sweet loveliness of Lichfield and Wells and Exeter with renewed delight. Amiens, Clermont, Narbonne are something more than human; it is awe, admiration, almost terror they excite; they seem superhuman; not built for mortal men by mortal men. There is nothing overwhelming or overpowering in the ancient churches any more than in the scenery of England; it is a little country, a peaceful, restful country; no Alps;

> "No grand Nature;
> All the fields
> Are tied up fast with hedges, nosegay-like;
> The hills are crumpled plains; the plains pastures;
> And if you seek for any wilderness,
> You find at best a park."

The English cathedrals were made for England.

THE DISCUSSION.

Mr. E. S. Prior, in opening the discussion on the paper, said Mr. Bond had given them a photographic, and not a superficial, view of the cathedrals; yet he had included many churches

that were never cathedrals. He thought he carried the comparison of archiepiscopal and monastic churches a little too far. Most of our cathedrals were originally monastic, built in connection with monasteries, and therefore could not be put upon the same par as French cathedrals, which were built as the crown of a city, and drew their impetus of building from the civic traditions of a great city. In comparing the western fronts the French were rather dark, and in our English climate they would have been darker still. He thought Wells avoided this. Mr. Bond had treated Wells front somewhat roughly. Also, in comparing the English cathedrals with the French it must be remembered that the latter were only built in a very small area—the Ile de France—so that many of the cathedrals Mr. Bond had included were not really to be considered as French. Mr. Bond called the case of the English sculpture hopeless; but it should be remembered that most had been destroyed by restorers. He himself did not think it hopeless. With regard to the man's insignificance in a French cathedral this grandeur was also to be found in Durham.

Mr. Stannus said he was entirely at one with Mr. Prior as to the grandeur of Durham. In regard to double transepts, these allowed of a number of chapels being placed in connection with the church which could not otherwise be attached, it being a necessity at that time in England of having the chapels face east. The French not caring so much about the eastern position of the chapels, clustered them round a chevet. He proposed a vote of thanks to Mr. Bond; Mr. Alexander Wood, Mr. A. S. Flower, and Mr. Seth-Smith also spoke.

The vote of thanks having been accorded, Mr. Bond in reply said he thought Mr. Prior had certainly made a point in regard to monastic cathedrals. Durham impressed from its being Romanesque. From more than one point of view Gothic was a decadence from Romanesque.

Professional Practice.

Birkenhead.—The new public baths erected by the Corporation were opened recently. The site of the buildings is on the south-easterly side of Livingstone Street, between St. Anne Street and Price Street. The main elevation is to Livingstone Street. Two entrances are provided—one for the first class and ladies, and one for the second class. The first class swimming bath is 63ft. by 24ft., with dressing-boxes along one side and one end. The second class swimming bath is 75ft. by 30ft., with dressing-boxes along both sides, so arranged that the tops form a gallery to be used for swimming galas, &c., and a large gallery is also constructed at one end of the bath. There are nineteen slipper baths, viz., twelve second class gentlemen's, three ladies', and four gentlemen's first class. A vapour bath, and a needle and shower bath are provided in connection with each of the classes of slipper baths. Salt and fresh water will be supplied to both slipper and swimming baths. There is a commodious laundry in connection with the building, fitted with steam-driven washing machine, hydro-extractor mangle, porcelain wash troughs, rinsing tanks, soap boiler, dirty clothes bins, folding-tables, &c. The laundry machinery is driven by a 4-h.p. vertical steam engine, and two Lancashire boilers 20ft. by 5ft. 6in. are used for supplying steam for heating and power purposes. In the whole of the building the various classes are accommodated with waiting-rooms, sanitary arrangements, &c. There is a caretaker's house in connection with the building, containing a commodious kitchen, sitting-room, scullery, and three bedrooms. The whole of the building is cleared, so that all the fittings can be easily examined. The building is constructed of brick, with red pressed brick and terra-cotta dressings, of plain but substantial appearance, and has been designed with special regard to light, air, and general sanitary details. Mr. Charles Brownridge, engineer, is the architect. The contractor for the erection of the building was Mr. James Merritt, of Birkenhead; the contractors for the boilers, heating apparatus, and laundry machinery, Messrs. Thomas and Taylor, Limited, of Stockport; and Messrs. Newton Chambers and Co., Limited, of Sheffield, have carried out the contract for supplying and fixing the salt-water storage tanks and filter. The cost of the building, including machinery, is about £11,000, and of the salt-water storage tanks and filter about £1,600.

Borgue, Kirkcudbrightshire, N.B.—The Free Church has recently been opened after having been, along with the manse, remodelled and improved at a cost of about £1,000. A new open-timber roof with pitch-pine hammer-beam principals have been put on the church, and the internal arrangement has also been improved, and a new platform, pulpit, and seating added. A new vestry has also been built convenient to the pulpit. The works have been executed by local tradesmen from the designs of Mr. J. A. Macgregor, architect, Castle Douglas, N.B.

Buntingford.—The restored Chapel-of-Ease of St. Peter has been opened as the Parish Church of Layston, or rather of Buntingford. Layston Church still stands on a hill half-a-mile outside the town of Buntingford, but very early in its history the parishioners preferred to live near the great highway of the North Road, and the town of Buntingford, like Royston, grew up without a parish of its own, but consisting of a thriving community situate in several parishes, but chiefly in Layston. Layston Church of St. Bartholomew has long since been in such a state of dilapidation and decay as to be quite unfit for public worship. The Chapel-of-Ease, St. Peter's, built about 1615, at the southern entrance to the town of Buntingford, also began to show the ravages of time to such an extent that restoration was urgently needed. The building was evidently at first rectangular in shape, but north and south transepts, and apse had been added. The south end formed the chancel. Thus the plain brick building became as it is at present, cruciform in shape, and was somewhat modified Gothic of the seventeenth century in style. The fabric has been overhauled and repaired, and retiled with the old tiles where possible. A new porch has been built, and a much needed vestry added. Internally the building has been replastered, the roofs boarded and stained. The old oak work has been utilised in the pulpit, choir seats and gallery front. Comfortable benches have been provided, and all rows placed one way. The floor is composed of wooden blocks, and all the seats in the nave and transepts are of pine and have been neatly stained and polished. Of the nineteen windows, seven are entirely new, but some are small, consisting of only one light. The larger windows have brick mullions. All the glass used is cathedral and of a greenish tint. The building is heated by warmed fresh air. The choir and chancel is paved with Minton tiles. In the sanctuary the old communion table is preserved. The reredos consists of a framework of alabaster mouldings enclosing three panels of Italian marble. On each panel there is an *opus sectile* inlay of blue Venetian glass joinery. This work has been admirably carried out by Mr. James Forsyth, of the Sculpture Works, Hampstead. The altar cloth has been renovated. The central window in the apse is fitted with stained glass, the subject represented being "St. Peter healing Æneas." This window is the work of Mr. Dudley Forsyth, of Hampstead. A new feature possessed by the chapel is a bell turret, where is hung a bell weighing two hundredweight. Below the turret is a space for a clock, facing the town. The cost of the bell and clock is estimated at £90. As yet the old organ will have to be used, but a movement is already on foot to obtain a new one. The total cost of the restoration and alterations is about £2,000. The work has been executed by Mr. Chas. Whyatt (Messrs. Gimson and Co.), of Royston, under the direction of the architect, Mr. William A. Pite, F.R.I.B.A., 11 Hart Street, Bloomsbury Square.

Dundee.—The Wishart Memorial United Presbyterian Church is now being erected, and will have seating accommodation for 700. The entrance will be from King Street. The stone dressings of the front will be of red stone. Owing to the surrounding buildings great care had to be exercised in arranging the interior so as to give ample light and good acoustic properties. The plan is arranged in one large nave, side aisle, and transept, with an end gallery next King Street. Halls and other accommodation will be provided in the ground floor, the halls being capable of holding 350 persons. The entrance to the halls and the gallery of the church will be by a door under the tower. The contractors for the work are Mr. Robert Laing (mason), Mr. F. C. Stocks (joiner), Mr. M. Lawless (plasterer), and Mr. W. Brand (slater). Mr. T. M. Cappon is the architect.

Flookburgh.—A new church has been erected to take the place of the old chapel-of-ease. The building is Transitional in style, and has been

PREMISES, NOS 33-35 HIGH STREET, ILFRACOMBE. ALLEN T. HUSSELL, ARCHITECT.

designed by Messrs. Austin and Paley, architects, of Lancaster. The cost has been about £11,000. The ground plan shows a nave, north and south aisles, chancel, south transept, entrance porch, and bell-tower at the west end. The building is of stone from the Home Farm quarry on the Holker estate, with Hutton Roof stone dressings and Yorkshire flagstone slates. All the windows, chiefly of lancet form, are of cathedral glass in leaded squares, with the exception of the three apse windows, which are of stained glass, executed by Messrs. Shrigley and Hunt, of Lancaster. At the east end, a door leads on the level to the vestry and heating room, which are below the organ transept and chancel, and from here also the organ is reached by a stone staircase. The bell-tower is approached by a door in its north face. The main entrance to the church is by a moulded porch in the Norman style on the south side near the tower. The nave, 62ft. by 22ft., is divided from the aisles by arcades of three bays, the pillars being alternately circular and clustered, and the aisles, 43ft. by 9ft., run the length of the arcades over which is a clearstorey lighting the nave. The pews are of oak, and are laid upon pine blocks on asphalt and concrete. The main roof is open to the timbers, whilst the ceilings of the chancel and apse are of stone, the former having a parapet with moulded corbels and coping, and the latter being stone groined. The chancel floor is paved with encaustic tiles and marble, and the back wall behind the communion table is of alabaster. The choir stalls are of carved oak, and the vestry fittings are pitchpine. There is a stone pulpit, and a limestone font. The credence and double sedilia are in the south wall, with stone seat and shelf. There are two chancel arches dividing respectively the nave and chancel and apse and chancel, the groins, of barrel vault shape, continuing the arch to the circular portion of the apse, which is a true groin with moulded ribs springing from circular shafts with moulded caps and carved terminations. All the aisles and passages are flagged. A new feature in connection with the heating apparatus is the entire heating of the roof, which will prevent down-draughts. The seating accommodation is for 400. The massive tower, surmounted by a saddleback roof, is 18ft. 6in. square inside, is divided from the nave inside the church by an arch, is lighted by chancel windows, and contains four bells. The angles of the towers have pilaster buttresses running up close to the corbelled plain ashlar parapet. The bells are four in number, and were made by Messrs. Taylor and Company, of Loughborough. The frames are of massive iron castings, standing upon and bolted to stout steel girders. The organ has been built by Messrs. Brindley and Foster, of Sheffield and London. The contractors not specified above were:—Mason, Messrs. A. Blair and Sons, Allithwaite; joiner, Messrs. Gradwell and Co, Limited, Barrow; plumber and glazier, Mr. A. Moorhouse, Kirby Lonsdale; slater, Mr. J. Chippendale, Grange; wood and stone carver, Messrs. H. T. Miles and Son, of Cark and Lancaster; marble worker, Mr. J. Hargreaves, Lancaster; ironworker, Messrs. Singer and Sons, Frome; lampsmith, Messrs. Hardman, Powell and Co., Birmingham; hassocks, &c., Messrs. Jones and Willis, Birmingham; heating engineer, Messrs. Seward and Co., Lancaster; stained glass, Messrs. Shrigley and Hunt, Lancaster; altar cloths, &c., Messrs. Watts and Co., Limited, London.

Ilfracombe.—The new premises in High Street, illustrated on the previous page, have been erected for Mr. A. C. Blake at a cost of about £4,000. They comprise four floors with basements and are faced with Lawrence's T.L.B. red-facing bricks, with Bath stone dressings and polished red Aberdeen granite pilasters to shop fronts. The contractor was Mr. F. J. Reed, and the architect Mr. Allen T. Hussell, both of Ilfracombe.

The Royal Society of British Artists are now holding their exhibition of pictures at the Suffolk Street Galleries, Pall Mall East, S.W., The president, Sir Wyke Bayliss, sends one work, "St. Mark's Venice," an interior of chancel and pillared arches in gold and brilliant colouring.

MATERIALS INFLUENCING DESIGN.

AT a meeting of the Edinburgh Architectural Society held on Wednesday last, Mr. A.F. Balfour Paul, president, in the chair, a lecture with the above title was delivered by Mr. J. A. Carfae. At the outset Mr. Carfae mentioned the advisability of using stone from local quarries not only on account of economy, but also for the sake of its fitness with the surroundings. No unnecessary labour should be expended upon a hard stone such as whinstone, and even squaring could with advantage be dispensed with. The selection of stone was daily becoming more difficult, and in many busy centres local quarries were being exhausted. The use of brick was consequently increasing, and for its treatment in design there was immense scope. There were many English examples of brick being well used.

In street elevations, on account of the requirements of modern shopkeepers, it was often necessary to begin the design at the first floor instead of at the ground level. Regarding the exposure of constructive material, it was impossible at the present day to leave many parts of construction, e.g., joisting, hearth, arches, &c., uncovered, and there was no harm in covering much of the framework of a building, such as iron and steel, so long as the covering suggested good construction. Iron standards in this way might be enclosed with brick and give the impression of a solid pier. Limmer rock asphalt was now in extensive use as a roof-covering, and there was no reason why inventiveness should not in time make flat roofs attractive. Cast iron was capable of much better treatment than it received at present, and for work which must necessarily be cheap was often preferable to wrought iron. In conclusion Mr. Carfae thought that with the new materials and the new machinery for working material, now at the disposal of the architect, there was a great future for design; and if the present generation was unable to accomplish much, it was at least preparing a way for its successors.

LONDON COUNTY COUNCIL.

AT last week's meeting the Improvements Committee recommended that the Council should contribute £270, one-third of the nett cost of the reconstruction by the Vestry of St. Martin-in-the-Fields of the steps in front of St. Martin's Church in such a way as to increase the width of the footway on the eastern side of St. Martin's Place to about 9ft. The Committee reported that the steps had been in a dilapidated condition for some time, and, owing to their condition and position, were the cause of frequent accidents. In consideration of the vestry undertaking the work, the church authorities would surrender without money payment the land to be added to the public way. They regretted that it was not possible at the present moment to increase the width of the carriageway, but any increase in the width of the thoroughfare at this part must be of great advantage to traffic generally. They could see no other way of obtaining a widening than by the scheme now proposed, as the National Gallery was on the other side of the road. Mr. Shaw Lefevre moved, as an amendment, that the recommendation be referred back to the Committee with instructions to take expert opinion as to the architectural effect of the proposed alteration, and to request the Vestry of St. Martin-in-the-Fields meanwhile to take no further action for carrying out the work. He declared that the scheme, if carried out, would be very detrimental to the architectural features of a church, which was one of the most beautiful in London, not only for itself, but by reason of its almost unique position. Sir H. B. Poland, Q.C., seconded the amendment, which was carried, on a show of hands, after a brief discussion.

The Council approved the estimates, amounting to £1,307,030, for various improvements in Mare Street, Goswell Road, St. John Street, Clerkenwell, Blackstock Road, Archway Road, Kentish Town Road, Nine Elms Lane, Battersea Rise, Blackheath Road, Blackheath Hill, New Road, and High Street and Gardener's Lane, Putney (see page 231 of last week's issue).

As many as 3,700 persons of the labouring class, it was reported, would be displaced by the construction of the Holborn to Strand street. It was proposed to provide accommodation for 1,000 persons on the Duke Street and Marquis Court site; for 799 in a lodging-house at the corner of Kemble Street and Drury Lane; for 1,681 on Reed's Brewery site; for 680 on the Herbrand Street site; and for 290 on the Millbank site. The Improvements Committee reported that they had every reason to believe that the scheme they suggested would have the approval of the Home Office. They recommended the Council to approve it. This was done.

Reporting on the proposal that a tramway should be constructed along the Embankment, the Highways Committee stated that it appeared to them that the scheme might raise considerable opposition, and so place difficulties in the way of the Council obtaining legislation to carry out its numerous other tramway proposals, which otherwise might be to a large extent unopposed. After giving the matter very careful consideration, they had arrived at the conclusion that it was not advisable to proceed with the scheme next session. They recommended accordingly, and the Council approved their action.

Correspondence.

Low Side Windows.

To the Editor of THE BUILDERS' JOURNAL.

BROMLEY, KENT.

SIR,—Although I am far from wishing to open in your columns a discussion on this vexed question, I nevertheless beg some little space for a reply to Mr. Johnston's letter in your issue for October 17th.

Mr. Johnston admits that documentary evidence of their use for confession is very uncommon; he quotes Bedyll's letter which refers *exclusively* to monastic establishments. This was noted in the "Antiquary" a short time ago in the course of a discussion on the same subject, and it is an objection as yet unexplained.

So far as my experience of Kentish churches is concerned, I cannot altogether agree with Mr. Johnston in his remark that these windows are the rule rather than the exception in country churches. In my own district, the following are the churches where I believe they do not exist:—West Wickham, Hayes (much restored), Bromley, Foot's Cray, St. Paul's Cray, St. Mary Cray, Crayford, Horton Kirby, Farningham, Keston, Aylesford, Ryarsh, Bearsted, Otham, Ash, Wrotham, Burham, Snodland, and Cheslfield. These churches exhibit architectural styles from Norman onwards, and form some slight evidence that the windows were not the general rule in West Kent at least.

If, then, this method of confession was so common during pre-Reformation times, why is there not a general distribution of the windows? Why are they found in secluded churches, and sometimes not in those buildings situated in towns, where the larger population would call for at least one confessor? If it was the custom for the confessors to travel in couples, why are there not more instances of double low side windows? Such instances are comparatively uncommon.

I challenge Mr. Johnston's theory for the origin of these windows. He says that they originated in the "barred and shuttered opening of the anchorite's cell." The very meaning of the word Friar (by whom Mr. Johnston says these windows were used) is in direct opposition to the whole spirit and practice of those who had forsaken the world for the small secluded cell. The thickness of the walls in which these windows often occur, would prevent that proximity of priest and penitent so much in keeping with the character of the confessional.

For Mr. Johnston's last paragraph I am particularly obliged; I had wrongly imagined the break in the walls to indicate the usual thirteenth century extension of the chancel.—Yours truly. J. RUSSELL LARKBY.

Builders' Notes.

The Fencing of Machinery.—At the Loughborough Petty Sessions recently, W. F. Harding, builder and joiner, of Loughborough, was fined £2 and costs for not properly fixing and guarding a planing machine, on account of which a workman was injured.

For Letting Four Uncertificated Houses Joseph Leech, a builder, was recently fined £4 and costs by the Wigan magistrates—£1 in each case. At Birkenhead William Davis was fined 10s. and costs in respect of each of three houses which had also been let without first being certificated.

The Building Trades' Exhibition will be held next-year at the Royal Agricultural Hall, London, N., from Wednesday, April 17th, to Saturday, April 27th. The last Building Trades' Exhibition was held in 1899, and was opened by Professor Aitchison, R.A., then President of the Royal Institute of British Architects, who was supported by the leading architects, engineers and surveyors in the country. It was admittedly the best exhibition ever held. The forthcoming one bids fair to be even better. The secretary is Mr. H. Greville Montgomery, of 43 Essex Street, Strand, W.C., to whom applications for vacant spaces should be made.

Mr. David P. How, builder and joiner Dundee, died last week at the age of 59 years. Deceased was well-known in building trade circles in Dundee and district. After serving his apprenticeship as a joiner with Mr. M'Intosh, Alyth, he returned to Dundee, and was for some time foreman to Mr. White, joiner, Ward Road, and in that capacity superintended the erection of the Drill Hall. About thirty years ago he started business on his own account, and since then had been closely identified with the local building trade. Of recent years he had devoted his attention specially to railway work, and erected, amongst others, the stations at Forfar, Brechin, and Stannergate. His interest in public affairs was limited to the incorporations, and he was for some time Box master of the Wright trade.

Municipal House Building at Sheffield.—Acting upon the resolution of the City Council at its last meeting, when by a vote of 21 to 19 a proposal was adopted that the Corporation should build shops in Angel Street, with workmen's dwellings above them, the Health Committee has resolved: "That the City Surveyor be requested to assess the fair saleable price of the plot of surplus land, containing 862 square yards, at the junction of Angel Street and King Street, to be appropriated by this committee in accordance with the resolution of the Council of the 10th October." Also "That the City Surveyor be instructed to prepare conditions and obtain competitive plans for the erection of a building on the surplus land at the junction of Angel Street and King Street, for occupation by selected small householders in the upper portion thereof, and saleshops on the ground floor and basement rooms thereunder."

Chester Cottage Homes.—At the last meeting of the Chester Board of Guardians, the chairman said a letter had been received from Messrs. M'Lellan Brothers, builders, asking to be released from their tender (see p. xii. of last week's issue) for the cottage homes which the Guardians decided to have erected at Saughall. A proposition had been before the committee that Messrs. M'Lellan should be released from the Saughall contract. An amendment was moved that they be released both from the Saughall and the Central Homes contracts. Messrs. M'Lellan's reason for asking to be released of the contract was that they had other work, in addition to being under contract to build Central Homes for the Guardians.—Mr. Morris moved the amendment which he had moved in committee—that Messrs. M'Lellan renounce both their contracts. These gentlemen wanted to take the best jobs, and he held that it was fair that if they refused to have one they should not have the other. The contracts should be put in the market again. After further discussion the amendment that Messrs. M'Lellan should either accept or renounce both contracts was carried by 18 to 6.

The Registration of Plumbers.—A national conference of plumbers was held at Birmingham last week. Mr. Robert Crawford, of Glasgow, representing the Court of the Worshipful Company of Plumbers, presided. In his address he said that after the efforts which had been made he thought they would come to the conclusion that they ought perhaps to abandon the attempt to obtain legislation through a private member, and to put pressure on the Government. It was a matter not so much for private effort as for Government legislation. Dr. Alfred Hill, medical officer of health for Birmingham, remarked that plumbing had a much more important effect on the public health than the majority of persons were aware. Several resolutions were passed, sanctioning steps towards the framing of a Plumbers' Registration Bill.

The Metropolitan Industrial Dwellings Company report that for the year ended September 25th last the nett profit during that period was £10,383, which is but a slight variation on the return of the previous two years, but about £2,000 more than was earned in 1896-7. The dividend on the Ordinary shares remains unchanged at 5 per cent., but the carry forward is £7,447, as against £5,688 twelve months ago. The company is still steadily building and has also acquired fresh land, which in time will no doubt be covered with houses. The company's property does not, of course, accommodate those the housing of whom is the real difficulty of the metropolis and of our big cities, but it must find suitable homes for many who otherwise would have to live in undesirable habitations without saving anything in the way of rent.

The British Fire Prevention Committee have decided to postpone the opening of their new testing station until after Christmas, as their testing operations are principally carried on in the spring and summer months and many of the firms who wish to have tests undertaken prefer to avoid the winter weather for research work of this description. During the first part of the current session the executive of the committee will hence be mainly occupied in dealing with tests already undertaken in the summer, but in respect to which reports have not yet been issued. They will also be preparing an analysis of the tests undertaken to date, for which there appears to be considerable request. The offices of the committee at Waterloo Place will again be available during the winter months as a reading room, and a file of about sixty technical journals from different parts of the world has been arranged for, whilst a small collection has also been formed in the reading room with a view to showing materials that have been subjected to tests.

Engineering Notes.

Extensions to the Union Infirmary, Londonderry, are being warmed and ventilated by means of Shorland's patent Manchester grates, patent exhaust roof ventilators, and special inlet panels, supplied by Messrs. E. H. Shorland and Brother, of Manchester.

A Novelty in Electric Lighting.—The Electric Lighting Boards, Ltd., is the title of a company which has been formed to develop an invention by which electric lamps can be moved from point to point without the need for special wiring. The device consists essentially of a board or a narrow strip made of a somewhat elastic composition in which are embedded a number of fine copper wires. The lamps are similar to those in common use, with the exception of two spikes or prongs which extend below the cap (no holders are needed). By this means the lamp can be stuck into the prepared strip at any desired point and will light up; or a plug may be stuck in and a lamp suspended from it. The invention is applicable to shop windows, advertisement boards, workmen's benches, theatres, and especially for any temporary lighting, such as that for balls, banquets, or bazaars. The company's showrooms and factory are at 18 Dean Street, Soho, W.; the registered office is at 7 Pall Mall, S.W.

The Headquarters of the Honourable Artillery Company in City Road, Finsbury, E.C., have been wired for the electric light by Messrs. Donnison, Berlyn, Sillem, and Co., of London and Liverpool. The fittings have effectively worked in them the arms of the H.A.C.

Electric Lighting of St. George's, Hanover Square, London.—The Vestry of St. George's, Hanover Square, has made an agreement with the Westminster Electric Supply Corporation, Ltd., for lighting the public thoroughfares of the parish with electricity. The installation is to consist, in the first place, of 600 arc lamps, the posts to be of the same design as those already erected near Victoria Station. The number of these will be comparatively small. The work is to be begun immediately, and to be completed, so far as the 600 arc lamps are concerned, by June 30th, 1902. The total cost of lighting the 42 miles of public ways contained in the parish is estimated at about £17,000 per annum, as compared with £11,000, the present cost of lighting with gas. For this additional expense the ratepayers will get from 15 to 20 times the amount of light which they enjoy at present. The annual cost of each lamp will be:—750 watts arc lamp, £32; 500 watts ditto, £22; 120 watts incandescent lamp, £4; 60 watts ditto, £3.

Law Cases.

Infringing the Building By-Laws.—At Leeds Police Court last week Mr. Herbert Wright Thompson, builder, 186 Harehills Lane, Roundhay, was charged with two offences against the building by-laws—namely, having erected four houses in Brownhill Terrace, Hudson Road, contrary to plans approved, and three houses in Brownhill Avenue without having obtained the necessary approval. Mr. C. C. Jolliffe, Deputy Town Clerk, appeared for the Corporation, and Mr. Arthur Willey to defend. Plans had been passed for the erection of back-to-back houses, but defendant, finding that he was restricted by the conditions of sale from building houses of the character approved, made certain structural alterations. Two sets of amended plans were submitted, but rejected. Defendant, however, still carried on the work. A fine of 40s. and costs was imposed in each case.

Fire-resisting Construction between Trade and Private Premises.—On Wednesday last Mr. Kennedy gave his decision in an appeal under the London Building Act, 1884, section 150, brought by Mr. F. C. Hoskins against Mr. B. Dicksee, district surveyor under the London County Council (see p. 240 of last week's issue). Mr. Hoskins is a builder, and in June last entered into a contract to take down and rebuild the "Horseshoe" beer and wine house, 87 Old Kent Road. The plans were approved by the licensing magistrates, and in due course a notice was sent to the district surveyor. It was proposed to make the doors leading to the passage and the stairs to the first floor of deal, and the ceiling of the bar of lath and plaster. The district surveyor served a notice upon him stating that the building came under section 74, subsection 2, as part was to be used for the purposes of trade and part as a dwelling-house, and therefore the ceiling, staircase, &c., must be made of fire-resisting materials. This was the matter in dispute. Appellant's counsel contended that the building did not come within this section, and in support of this he quoted *Carritt* v. *Godson* (1899 2 Q.B., 193), in which it was held by the Divisional Court that a fully-licensed publichouse was not a building within the meaning of this section. A distinction was made, on behalf of the London County Council, between a fully-licensed house and a beerhouse, as a keeper of the latter was bound by law to reside upon the premises. Mr. Kennedy said he could not satisfactorily distinguish this case from *Carritt* v. *Godson*, and the appeal would therefore be allowed, with £5 5s. costs. On the application of Mr. Andrews, the magistrate consented to state a case.

Keystones.

The Work of Completing Truro Cathedral will be begun shortly, the final contracts having been signed.

The Memorial to Viscount Shannon in Walton Church is being restored by Mr. F. J. Williamson, of Esher.

St. John's Church, Great Marlborough Street, London, is having new chancel screen, pulpit, and choir stalls added.

Huddington Church, between Worcester and Droitwich, is being repaired and renovated. All the old features worth preserving are being carefully retained by the architect, Mr. Ford Whitcomb, and £1,050 is required to complete the work.

Closing of the Paris Exhibition Adjourned.—The French Government have decided to prolong the Exhibition for six days. Instead of closing, as it was to have done, on Monday, November 5th, it will remain open until Sunday, November 11th.

A new Board School at Dulwich was opened recently. Accommodation for 1,084 children is provided. The school is in Grove Vale, East Dulwich. The cost of the site was £2 18s. per head, as against the average of £7 1s. 7d. for the whole of London, and the cost of the building was £25,000, or £23 per head, making the total cost per head £26.

The Parish Church of Watlington, near Downham Market, dedicated to St. Peter and St. Paul, has recently been reopened after considerable renovation and repair. The church, or some part of it, dates back to the fourteenth century, and presents many interesting features. During the process of restoration a piscina and two aumbries were discovered in the north wall of the chancel, and it is thought that there may have been a small chantry chapel on that side. The work has cost about £1,400.

A New Police-court at Enfield has been erected on Windmill Hill by the Middlesex County Council, at a cost of between £6,000 and £7,000. This practically completes the scheme for the provision of magisterial courts in the county, each district being now supplied with properly equipped courts. Altogether the County Council has spent within the last five years about £35,000 in providing buildings for the transaction of magisterial business in place of rooms at public-houses and schools.

The Old Church of St. Gregory, Tredington, which is situate about half-way between Stratford-on-Avon and Shipston-on-Stour, has been reopened after careful restoration. The late Sir Arthur Blomfield prepared the plans for the renovation of the building. The cost has amounted to nearly £4,000. The ancient character of the church has been shown during the work by the discovery of Saxon and Norman remains, and Gothic and Jacobean work is represented in various parts of the edifice. The pulpit is considered to belong to the Elizabethan period. A new carved oak altar has been installed.

The Old Churchyard Cross at St. Thomas-à-Becket's Church, Wolves Newton, Monmouthshire, has been restored as a memorial to the late Mr. G. K. Bryan, of Wolves Newton; only about 5ft. of the shaft of the ancient cross remained, and it was decided to utilise this, but upon examination it was found the base and steps were in such a bad state that the whole had to be removed and reset with some new steps and tabling from the quarries at Pontysesion, near Tintern. The head of the cross is of fine red Dumfriesshire stone, and it is 6ft. 11in. from top of shaft to top of finial. There are four panels on the west side; the crucifixion is represented on the east, St. Thomas-à-Becket standing before the altar; on the north the Tudor Rose; and on the south the Canterbury bells. The whole is surmounted by a canopy and crocketted pinnacles, the total height being 22ft. 6in. The architect is Mr. C. E. Ponting, F.S.A., of Marlborough, and the work of restoration was carried out by Messrs. A. Palmer and Sons, of Bristol.

A Working Men's Club at Rock Ferry was opened last week in Bedford Road.

A new Courthouse and Police Station at Lythan is to be erected by the County Council.

A new Science and Art School at Newark has been erected in commemoration of the Queen's Diamond Jubilee.

A new Town Hall for Barnsley.—The Barnsley Town Council have decided to purchase for £4,100, from Mr. C. Woodruff, property known as the Manor House Estate, adjacent to the present Town Hall, as a site for a new building.

Architectural Association of Ireland.—At a general meeting of the members held on October 23rd, the President, Mr. Frederick Batchelor, in the chair, a vote of congratulation to Sir Thomas Drew on his election as president of the Royal Hibernian Academy was adopted. Mr. R. M. Butler then read a paper on "Architectural Association Excursions."

A new Mission House at New Cross, S.E., in Pagnall Street, was opened last week by the Princess Christian. The architect is Mr. William A. Pite, F.R.I.B.A. Not an inch of space inside has been wasted. There is a large hall for services and meetings, there are committee rooms and classrooms, a gymnasium fully equipped for the Church Lads' Brigade, a soup kitchen, and a convenient flat for a church worker. The building has cost nearly £4,000.

New Sunday Schools at Beeston, in connection with the Beeston Church Valley Mission, have been opened. The building accommodates about 450 persons. In addition to the hall in which the ceremony was held there is at the rear a large classroom, capable of seating between 70 and 80, the whole having been erected (on land purchased for £350) at a cost of £1,400, half of which sum, however, has yet to be raised. The main hall is 80ft. long, 35ft. wide and about 30ft. high; the classroom 35ft. by 18ft. There is a large platform at one end of the hall, which is lighted by 24 incandescent burners, and heated by means of hot water.

Glasgow Technical College Architectural Craftsmen's Society held its second meeting on Friday last, when Professor Henderson, D.Sc., M.D., lectured on "Chemical Notes of Building Materials." The lecturer pointed out the various constituents of the atmosphere which acted on materials with regard to their permanency, mentioning elementarily: 1. Water vapour; 2. Carbonic acid and oxygen. Metals were shown to be the most susceptible to atmospheric influences, because of their undergoing corrosion due to oxygen, and in the air of towns this action was greatly promoted, owing to the presence of injurious acids. Regarding iron, the various methods of protecting with their merits, and the precautions necessary to their proper application, were clearly demonstrated, and special attention was directed to the galvanic action set up between certain metals, such as tin and iron on exposure to the air, which action aids the corrosion of the iron. In galvanising with tin this was occasioned by any flaw in the coating; but so long as the coating was intact, galvanising by means of zinc, tin, or nickel was effectual as a protection to iron. A galvanic couple was set up by the contact of iron and lead in the fixing of iron railings, and sulphur was also considered to be objectionable. Cement was the most suitable for this purpose. Regarding lead and zinc, the lecturer stated that great care should be exercised in using these for the storing and conveying of water, and on no account should they be used in the construction of cisterns for water to be used for drinking or cooking purposes, as zinc is dissolved by soft water, and lead, when exposed to air and water, produced a compound of lead, soluble in water, and poisonous. Slate for cisterns was recommended. The lecturer dealt further with various metals, stone, and wood, and remarked in the case of stone that the more compact it was in structure the less likely to be affected by external influences. In conclusion, attention was drawn to the elementary facts dealt with as being of great importance, though too often overlooked.

A New Church at Forest Gate, to be dedicated to St. Edmond the King and Martyr, is being erected.

A Water Fountain has been built, at the expense of Mr. Passmore Edwards, in Christ Church Churchyard in the Blackfriars Road, London.

As a Memorial to the Late Sir William Hunter it is proposed to place a stained-glass window in the chancel of Cumnor Church. Should funds admit, replicas of a bust in bronze of Sir William Hunter by Mr. Hamo Thornycroft, R.A., will be presented to the Indian Government, and to the Indian Institute, Oxford.

The Wallace Collection during the winter months of November, December, January, and February will be open every Monday at 12 o'clock instead of at 2 P.M., as hitherto arranged. To avoid inconvenience to the public, it is desired to point out that children under eight years of age are not admitted under any circumstances. Under 12 years of age they must be accompanied by adults.

The Tabard Inn, Southwark, so imperishably associated with Chaucer's "Canterbury Tales," was one of the famous London hostelries which retained most of its ancient features until a comparatively recent date. It stood in the High Street of Southwark, about midway between St. George's Church and London Bridge, and nearly opposite the site of the old Town Hall. The original inn, as it was in Chaucer's time, existed in 1602, but in 1874, when it was demolished, all its quaint old features had vanished. A good deal of it, however, dated from the time of Queen Elizabeth.

Loftus-in-Cleveland Parish Church is being renovated, and a new and enlarged chancel added at an estimated cost of £2,700. The architects are Messrs. Clark and Moscrop, of Darlington, and the contractors for the mason work, joinery, and cabinet work, Messrs. Bastiman Brothers, of Middlesbrough. The whole of the stonework used in the new portion will be obtained from the Marquis of Zetland's quarries. The pulpit will be of stone. The whole of the windows, of which there are 20, will be traceried in stone, and filled with cathedral-tinted glass.

A new Vicarage House at Clevedon was opened recently. The walls of the vicarage house are of local Pennant stone to the first floor, and from there of brick. The dressings are of Box ground stone, and the roofs are covered with Broseley tiles. The main staircase is of pitch pine, with oak handrails. Wood blocks are laid to hall, passages, parish room, pantry, and kitchen floors. The site is a very commanding one, overlooking the Bristol Channel, and having a good view of the Mendip Hills. The work has been done by Mr. W. A. Green, a local contractor, at a cost of £2,500, from designs by and under the superintendence of Mr. F. W. Hunt, architect, London, Mr. Hocking being clerk of the works.

New Baths at Poplar, situated in Glengall Road, Millwall, erected at the instance of the vestry of All Saints', Poplar, were formally opened last week. The site of the new baths has a frontage of 110ft. to the Glengall Road, and a total depth of 230ft., the area being about half an acre; and as the new building has a frontage of 80ft., there is room for a walking-way 10ft. wide on the west side, and for a cartway 20ft. wide on the east side. There are seven entrances, while the main corridor in the centre of the building is a sort of internal street, from which doors open into the various departments. In addition to the large swimming bath there are men's second-class private baths for 26, men's first-class for nine, and women's baths for five, or 40 slipper baths in all. The pond of the swimming bath is 75ft. long by 35ft. wide, with water 3ft. 6in. deep at the south end and 6ft. 6in. at the deepest part. Wooden dressing-boxes with dwarf doors in front run round the bath on the level of the platform, and there is a gallery on all sides. The cost of the baths will be about £10,400. The materials are red brick, faced with glazed brick and Portland stone. The architects were Messrs. J. S. and F. Clarkson, and the contractors Messrs. F. Thorne.

A new Wesleyan School-Chapel at Appley Bridge has been erected at a cost of about £700. Mr. R. Holt, of Liverpool Road, Appley Bridge, is the architect.

A new Bank at Khartoum.—On the 27th ult. the foundation-stone of the Khartoum branch of the National Bank of Egypt was laid. The contractors are Messrs. Edgar Kirby and Co., of Cairo and Alexandria.

The Death of Mr. W. F. Wakeman, Fellow of the Royal Society of Antiquaries of Ireland, occurred last week at the age of 78 years. Mr. Wakeman wrote considerably on antiquarian subjects, and was an accomplished artist.

A Memorial Tablet to Turner has been placed on the painter's house, now No. 118 Cheyne Walk, Chelsea. The tablet is the design and gift of Mr. Walter Crane, and has been modelled and cast in lead by the Guild of Handicraft.

New Parish Rooms of St. Thomas's Church, Eastville, were opened recently. The building consists of two large and lofty rooms and the necessary offices. The upper room is approached by a wide staircase from the main entrance. The rooms have been built at a cost of about £2,200.

New Companies.

Bermondsey Wharves Company, Limited.

This company was registered on October 19th with a capital of £11,000 in £1 shares to adopt an agreement with Susannah Kemp, and to carry on the business of timber and hardware merchants, wharfingers, dock owners, &c. The first directors (to number not less than three nor more than seven) are to be appointed by the subscribers.

Western Valleys Cottage Company, Limited.

This company was registered on October 17th with a capital of £5,000 in £10 shares to acquire land and buildings in the United Kingdom, to erect houses, cottages, and other buildings, and to carry on the business of land, house, and property owners, auctioneers, surveyors, &c. Registered office: Ffrywd Villa, Mountain Ash, Glamorganshire.

W. Beardsmore, Northampton	1,247	* Accepted.	

CONTRACTS OPEN.

TO BUILDERS.

Persons desirous of TENDERING for the ERECTION of a New BOARD SCHOOL, to be known as the CALSTOCK TOWN BOARD SCHOOL, at Calstock, in the County of Cornwall, for the Calstock School Board, can inspect the plans, specifications, and general conditions for the same, prepared by Mr. H. J. SNELL, Architect, The Crescent, Plymouth, on application to the Architect, or to A. J. ROWE, Clerk to the Board, Calstock.

Tenders (endorsed) are to be sent to me (on forms to be obtained from the Architect) on or before FRIDAY, the 9th NOVEMBER.

The Board do not bind themselves to accept the lowest or any Tender.

A. J. ROWE.

Calstock, October 1900.

URBAN DISTRICT COUNCIL of WALKER, NORTHUMBERLAND.
DUST DESTRUCTOR.

The Urban District Council of Walker invite TENDERS for the ERECTION, complete, exclusive of buildings, of a 2-unit DUST DESTRUCTOR of the Meldrum type, including Steam Boilers, Feed Heater, Water Tanks, Piping, &c., in accordance with the specification prepared by their Engineers. Specifications and form of Tender can be obtained on forwarding to the Engineers, Messrs. HANDCOCK AND DYKES, 1 Victoria Street, Westminster, London, S.W., the sum of Two Guineas, which will be returned on receipt of a bonâ-fide Tender. Sealed Tenders, endorsed "Dust Destructor," to be delivered to the undersigned on or before NOVEMBER 12th.

T. M. STURGESS,
Clerk to the Council.

5 St. Nicholas Buildings,
Newcastle-on-Tyne,
October 1900.

COUNTY BOROUGH of DEVONPORT.
ELECTRICITY WORKS BUILDINGS.

The Corporation of Devonport are prepared to receive TENDERS from contractors having experience in public works for the ERECTION of ELECTRICITY WORKS BUILDINGS, comprising engine-house, boiler-house, pump-house, all necessary excavating, pumping, concreting, steel construction, pile driving, and other works in connection with the new buildings to be erected on Newport Quay, Newport Street, East Stonehouse.

Drawings and specification may be seen, and forms of Tender and bill of quantities can be obtained, on application to the Borough Electrical Engineer, Technical Schools, Devonport, on payment of a deposit of 3 guineas, which sum will be returned on receipt of a bonâ-fide Tender. The Corporation do not bind themselves to accept the lowest or any tender, and they reserve to themselves the right of accepting the whole or any portion of a Tender, and they will not make any allowance for or in respect of any expense incurred by the parties tendering.

Tenders must be filled in the form supplied, sealed, and endorsed "Tender Electricity Buildings," and must be sent in so as to reach me not later than NOVEMBER 2nd, 1900.

A. B. PILLING,
Town Clerk.

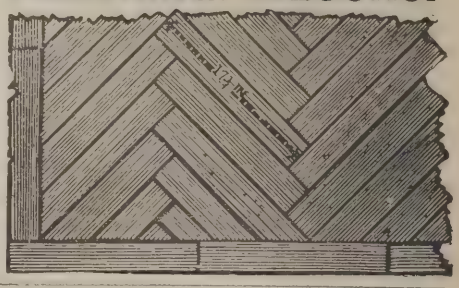
Municipal Buildings,
Ker Street, Devonport.

SPENNYMOOR URBAN DISTRICT COUNCIL.

The Spennymoor Urban District Council invite TENDERS for the ERECTION of an ISOLATION HOSPITAL in Merrington Road, Spennymoor.

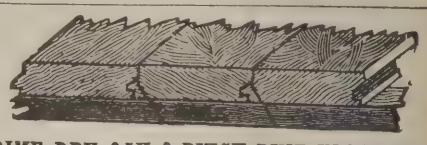
Plans and specifications may be inspected at the Surveyor's Office, Silver Street, Spennymoor, any day up to November 17th, between NINE a.m. and TEN a.m., and on Mondays and Fridays from NINE a.m. to FIVE p.m.

Forms of Tender can be obtained from the Surveyor, Mr. G. W. ROGERS, A.M.Inst.C.E., Spennymoor.



Sealed Tenders, endorsed "Tenders for Isolation Hospital," must be delivered at my office on or before MONDAY, NOVEMBER 19th.

The Council do not bind themselves to accept the lowest or any Tender.



F. BADCOCK,
Clerk to the Council.

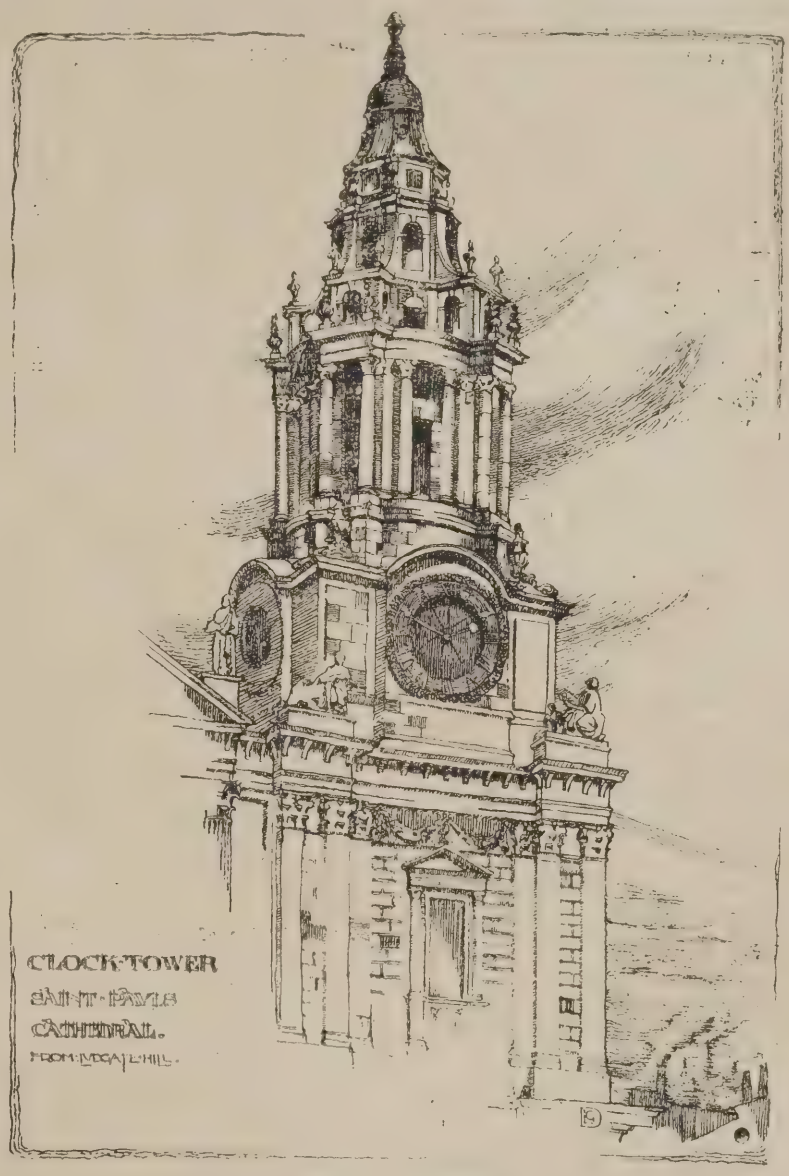
THE BUILDERS' JOURNAL & ARCHITECTURAL RECORD

NOVEMBER 7, 1900. No. CCC.

EFFINGHAM HOUSE, ARUNDEL STREET, STRAND, W.C.

An Architectural Causerie.

An Underground Architecture.



IT is certainly novel, but the idea might be taken to be a degeneration back to the days when—particularly in Asia—whole tribes and nations hid themselves in a subterranean world. Still America may be the pioneer of a modern underground architecture. In the great cities the sky-scraping buildings have about reached, both in the eyes of the law and as regards their physical possibilities, a maximum of altitude: is it therefore chimerical to think of a new era with buildings reaching below the surface to an equal distance? Even now progress is being made towards this end; for instance, in the underground railways, underground street-crossings, underground sanitary conveniences, and a variety of underground workrooms in the cellars of our business premises. The stress of modern life demands the compression of everything into the smallest area, and although much is bound to be achieved in the way of improved transit and communicative facilities, still the tendency to an underground architecture is strong. Of the advantages to be derived, one would be the hiding away from sight of all purely utilitarian and ugly, though necessary, businesses. How glorious to have a city with none of the industrial wreckage we see in all our large cities to-day! An underground building era would allow all such work as this to be carried on out of sight and sound. With the aid of the electric descender (a new equivalent of the elevator) far quarters of the underground world would be easily and quickly reached. There would be no sunlight, of course (alas! for this), but electricity would afford ample illuminative power, and by the aid of efficient air-shafts excellent ventilation could be obtained. And how quiet and restful the business offices would be, away from the rattle and bustle of the overhead world. The idea is a new solution of the housing problem. It would certainly give us an economy of building space. An American architect lately said: "It may be a long time hence, but I believe the time will come when there are as many buildings ten storeys below ground as there are that number above the surface of the earth." But what of Mr. H. G. Wells' underground race?

G. W. H.

Dirty London.

THAT London is an important city we all know; that it is beautiful may be questioned; that it is dirty is certain. There is a peculiarly destructive character in its mud when splashed upon clothing; an inky blackness of colour, a greasiness of texture spread over streets and walks in wet weather, an amount of refuse lying about in dry which a provincial town would not tolerate, whilst everybody has noticed the extraordinary quantity of paper always blowing and drifting about. To these amenities may be added rags of all materials and every colour under the sun, repulsive and dangerous. The great river is none too clean, though considerably improved since the system of sending the solid refuse a considerable distance out to sea was adopted. The Association of Cleansing Superintendents of Great Britain has been discussing the question of street-cleansing, and some valuable suggestions were made. The subject cannot be too often discussed; it deeply affects the public health and comfort. Mr. Brechin, of Glasgow, describes the latest developments of street-cleansing in that city. One of the most important is the washing down of the streets by the hose, a system pursued on a great scale for many years past in Paris; waste paper is not only picked up out of doors, but regularly collected from mercantile offices; clinkers from the destructors are sold and find a ready market. Mr. Smith, of Liverpool, read a paper on the use of motors for street watering and dust removing, and a resolution was passed in favour of that system. A conference upon similar lines, or perhaps a succession, might be held in London; there is room for such gatherings. It is generally assumed that Paris, a city of pleasure under a brilliant sky, is "naturally" kept up to a high standard of cleanliness, whilst London, a city of business, in a foggy climate, is no fit subject for elaborate street cleaning. But such remarks are seldomer heard now than formerly, and a vigorous cleaning-up of the streets, such as we do sometimes see in parts of London, always meets with the approval of the public. It should be permanent, however, and extend to the whole area of the metropolis.

DRAWN BY L^R G. DETMAR.

The Average Guide-Book.

THIS is pre-eminently the day of the guide-book. The windows of the discount booksellers are filled with them: guides to every conceivable and inconceivable place—to places you know, places you don't know, and places you don't want to know and wouldn't visit if you were paid for it. A much-travelled age, indeed, when we find six rival guides to one place competing for our favour at any price from six shillings to six pence! And what manner of guides are they? Murray, the archæologically-inclined, we know, and the more matter-of-fact Baedeker; but after them comes a horde of strangers whose works, compiled, one would say, from an examination of them, rather from their predecessors and from a desultory course of reading in the British Museum than from a personal knowledge of the places dealt with, form amusing reading to the critic if not instructive matter for the tourist. The sixpenny guide-book is upon us and our withers are cruelly wrung at its architecture in especial and its cheap rhapsodies in general. It is, to the

minds of these uninstructed writers, often a sufficient description of an ancient building to describe it as "Gothic" or "Classic." They are quite reckless, these fellows, of styles or periods; gargoyles or corbels to them are interchangeable terms, describing the same thing, and a crypt is but dimly seen to be something different from a chair. Then, too, your genuine guide-book writer is no pessimist. He is, on the contrary, an optimist of the most advanced type, and sees the world at large, and the places of which he treats in especial, in hues as roseate as the summer dawn. No place so abject, so dull, or so bedevilled with everything that is objectionable, but he will find something (and generally a good deal) to say in its favour, and in the most outworn *cliches*. He has a brief, and like a conscientious advocate, does his best for his client. He is great on the would-be heroic style and rounds up the tourist before mouldering castle or venerable abbey with "Do we not see the centuries passing in procession before us in their long chivalric train telling of"—anything you please, as the humour takes him at the moment. We, however, do not see; and small blame to us when, reading for the twentieth time of rocks "piled up as though by Titan hands," we refuse to proceed further. The inventor of that simile, long years ago, has a great deal to answer for, and so has he who, standing in some unexpected solitude within ten miles of crowded London, first exclaimed how difficult it was to realise that the mighty hive lay so near. For fully fifty years that exclamation has been dragged out and made to do duty in every conceivable and inconceivable place, and now deserves, but does not obtain, a well-earned rest. On the contrary, in a recently-issued guide to Surrey we find it once more, and in this latest instance reduced to absurdity in the phrase, "a dense volume of smoke rolling away for miles was illuminated at its windward extremity by a bright patch of flame. Looking at this from a pine-covered eminence, it is hard to realise that Fleet Street is less than 40 miles off." Leaving aside the odd conjunction of past and present tense which would have made the proximity of a Board School of advantage to that writer, we are left to wonder at the imaginativeness he displays, and rather fancy that the ordinary man *would* most keenly realise that 40 miles divided him from town and would delight in the realisation. C. J. H.

The Late Mr. Young. It is with great regret that we announce the death of Mr. William Young, F.R.I.B.A., who died on Thursday last (at the age of fifty-seven years) at his residence in Putney of acute pneumonia after five days' illness. Though never a strong advocate for Gothic, at the commencement of his architectural career he supported the school of Burgess, but later in life he gave himself wholly to Classic architecture, and produced such buildings as Gosford House (for Earl Wemyss), the Glasgow Municipal Buildings, and Chelsea House, to mention only three; his latest large design was that for the new Government buildings to be erected in Whitehall. He was elected a Fellow of the Institute in 1891. In our issue for June 18th, 1895, we published an illustrated article dealing with the work of Mr. Young; in the issue for the following week is shown a mantel in the dining-room of Boveney Court; while since then of the deceased's designs we have published those for the staircase at Gosford House (August 6th, 1895), plans of Glasgow Municipal Buildings (January 14th, 1896), and the new War Office (April 12th, 1899). Mr. Young was an able architect and a close thinker on the higher ethics of life, and the loss which the profession has sustained by his death will be widely and deeply felt.

On Reflection.

Remarkable Discoveries. MR. A. J. EVANS and Mr. D. G. Hogarth (director of the British School of Archæology at Athens) are to be congratulated on the remarkable and valuable discoveries which have been made in Crete, full particulars of which are given on another page. The substantial truth of early tradition is confirmed by the proofs now produced of the high state of civilisation which existed in the city of Minos. The mythical is becoming the actual. The "House of Minos," the Cretan god of the Double Axe, is without doubt the Labyrinth of later tradition, the home of the fabled Minotaur. For the completion of the whole scheme of excavation the sum of £5,000 was needed, but when work was commenced last year barely £500 had been raised by private subscription. Half of this went to assist one of the writers in the excavation of a site at Kephala, and the other part was apportioned to Mr. Hogarth for the exploration of the prehistoric town and tombs of Knossos and of the Cave of Zeus on Mount Dicta. In addition there was a supplementary grant of £200 from the income of the British School at Athens, and of a sum for the payment of an architect. And with these restricted means, see what has been done. Fresco paintings have been found that excel any known examples of the art of Mycenaean Greece, a painting of a youth gives us the first real knowledge of the race who produced this mysterious early civilisation, a palace has been found beside which those of Tiryus and Mycenae appear insignificant, a veritable Ægean Pompeii has been discovered, and considerable light has been thrown on the first development of high art, the origin of letters, and the earliest of civilisations. The British School at Athens has a Government grant of £500 a year (small enough in all conscience). For the Cretan Exploration Fund at least £3,000 is needed, and we earnestly hope, now it has been shown what valuable discoveries will yet be made, that the Fund will receive a support more adequate for its work and more worthy of the greatest nation the world has seen.

The Shrine of Shakespeare. AFTER a foolish controversy with Mr. Hall Caine, Miss Marie Corelli is now disputing with Sir Theodore Martin about the latter's proposal to erect an alto-relievo of his late wife (formerly known on the stage as Helen Faucit) in the chancel of Holy Trinity Church, Stratford-on-Avon (commonly known as Shakespeare's Church). There has been a mass of correspondence in the columns of the "Morning Post," and it is very difficult to pick out and arrange the facts. Sir Theodore says that it is now about a year since he first announced his proposal. At that time he took steps to ascertain the feeling of Stratford on the subject and found it favourable, the vicar himself cordially approving of the memorial being placed in the chancel. The Bishop of Worcester granted a faculty and, under the direction of Messrs. Farmer and Brindley, the final arrangements have been made. Miss Corelli now steps in and calls for a halt, flatly denying almost all the statements of Sir Theodore Martin. Says the novelist: "It is still fresh in the memory of the town that the vicar was absolutely bullied into accepting the marble pulpit Sir Theodore has erected to the memory of his wife, and was insulted because he made a bold stand against its singular unfitness for the character of Holy Trinity Church. The quarrel between the vicar, Sir Theodore Martin, and Sir Arthur Hodgson was hot and fierce, but the vicar had the intellectual advantage of being able to keep his temper, while the two other gentlemen lost theirs, and a good deal of dignity as well." Sir Theodore asserts that there happens to be a vacant space in the chancel fitted to receive the memorial. Miss Corelli says there happens to be nothing of the kind: "on the contrary, to make room for the proposed monument a fine old brass memorial plate of the Clayton family will have to be displaced and cut about, and the living descendants of that family, not having been asked to give their permission for this defacement of their property, are taking legal action against it." We are, however, glad of the dispassioned remarks of Mr. W. H. Wilkins, F.S.A., who points out that though there are memorials in the chancel other than that to Shakespeare, these are so unobtrusive that the ordinary visitor is hardly aware of their existence; and it is, therefore, perfectly true to say that Shakespeare's memory reigns supreme in the chancel. The alto-relievo is proposed to be placed within the altar rails and right opposite the immortal poet's bust. This would undoubtedly be a mistake. One of the London newspapers has recommended to Miss Corelli the advice of St. Paul as to the relations between ladies and churches, but, despite the fact that she has made several foolish, wild and incorrect statements in the course of this controversy, we feel bound to side with her on the main issue. It rarely seems to be remembered that a memorial in any building has to be considered in its relation to the architecture; the neglect of this truth furnishes us with so many buildings stocked like a monumental mason's yard. Sir Theodore Martin's statement that there is no place in the Stratford Church where the memorial can be well seen except the chancel is contradicted by the vicar's statement that there is a suitable vacant place on either side of the great west door. We might mention in conclusion that we hardly see the necessity for Sir Theodore to erect two memorials to his wife in the same church.

The First Garden City. ABOUT a year ago our columns were open to a correspondence on the merits of the Garden City Association, which had then just been formed under the direction of Mr. Ebenezer Howard. The Association now has 352 members, and has so fully developed its scheme that a resolution has been adopted for forming a company, with a capital of £100,000 in £1 shares, to found the first garden city. A suitable estate would be selected and would be laid out in the most approved manner, especially with the object of avoiding overcrowding. Manufacturers, traders and workpeople are to be attracted there, the rents from the various tenants (who would be the chief builders) would be used for forming roads and building schools, &c.; and thus we should have the model town. Mr. Blashill, the late superintendent architect to the London County Council is opposed to the present system of housing and says that it costs more than £50 a head to clear insanitary areas—the former tenants not returning to the new houses, but going away to overcrowd other districts. The scheme of the Garden City Association is worth trying, though on the surface it may appear rather Utopian. Still, the solution of the housing problem will not be accomplished on paper, and all practical attempts deserve support. It is very easy to talk about the necessity to first reform the man and then his house, to disparage every proposal, and then to *laissez-faire*: in the meantime thousands of men, women and children are living in houses not fit for dogs. New towns built purely for commercial ends are not novelties, and we therefore wish the first garden city the success which its enterprise deserves.

MR. WALTER G. PENTY.

MEN WHO BUILD.

No. 61.—Messrs. PENTY and PENTY.

IN dealing with the work of modern architects whose work carries with it some claim to distinction, it is with great pleasure that we have to consider the work of Messrs. Penty and Penty, of York. Mr. Walter G. Penty, the senior member of the firm, commenced to practice in 1873; the present *personnel* consisting of Mr. Walter G. Penty, F.R.I.B.A., and Mr. Arthur J. Penty, father and son.

The works belonging to the first years of the firm's practice, ending with the middle of the 'eighties, exhibit the Gothic characteristics that so largely mark the architectural undertakings of that era, when the revival of mediævalism was yet forceful and had not spent itself upon efforts to achieve the impossible and to bring back the era of chivalry. To this period belong such important works as the fine houses of "Burnholme," York; "Booklands," Selby; the restoration of Middlethorpe Hall and Alne Hall; and the pleasing red-brick building erected for the York Institute of Art, Science and Literature—now the home of the York Public Library—a building whose spacious and well-lighted rooms might form excellent object-lessons in library construction.

Turning from the cheerful ruddy elevation of this building, in so bright a contrast with the grim and sooty would-be mediæval walls of York Castle opposite, we find within a short distance in the streets of York City such works as the buildings for the York Liberal Club and a tall block of business premises in Coney Street, marking the beginning of the second period of Messrs. Penty and Penty's career; a selective period which, while perforce following the trend of taste in architectural design, has distinctive personal and local features. It is a nice point how far the architect practising in the provinces can allow himself to withstand the suggestions of clients who, taken captive by fashion (which, we all know, rules architecture as greatly as it does millinery), will have fashionable architecture or none at all. The wise man is he who, knowing the folly of kicking against the pricks, saves his practice and his artistic conscience at the same time by adopting the fashion and adapting it. Hence we find, in the second Penty period, such suggestions from the then current amalgam of Elizabethan, Queen Anne, and Early Georgian ideals introduced by Mr. Norman Shaw, as the pleasing red-brick and half-timbered, gabled "Bay Horse" inn in Marygate, York; the "Tile House," St. George's Place; "Rosenlaui," Clifton; "Aldersyde"; and "Dilston House," Lawrence Street—to which list may be added premises for Messrs. Adams and Co., sanitary engineers, at Peasholme Green; business premises in Skeldergate; the residence called "Kenilworth," in St. George's Place; a coffee tavern for the York Coffee Tavern Company in Walmgate; additions to Barkston Towers, Tadcaster; and that more recent work, "Langbaraugh," Fulford Road. Given, however, the first cause, the compelling influence, we find in the personal handling of that then fashionable style many interesting details of plan and design that well repay a special tour of inspection. Thus, at the "Tile House" just mentioned, which we illustrate, can be seen, even in this photographic view, a little detail which reveals at once that rare combination, the artist and the practical man. The detail to which we refer is the lighting of that pretty feature, the porch, continued as a room to the right by what we may call, for want of a better name in this connection, a dormer window. This renders that feature of the shaded porch possible, while lending light to what would otherwise be the somewhat darkened hall within. Were this porch or loggia away, however, this south part of the "Tile House" would yet be a pleasing and an interesting composition, wearing that air of solid and yet picturesque importance which a heaped-up mass like this gives. Light—abundant light, it will be noted, from the scale and disposition of the windows—is an especial and grateful feature of this interesting residence.

While we are on the subject of details, it may not be amiss to turn aside for a moment to note the charming door-head for the "Old Grey Mare" inn at Clifton, a remodelled house in that northern suburb of York. It speaks for itself: a fine work suggested obviously from old examples, but beautifully rendered, with a little effigy of the "Old Grey Mare" standing within the shell.

"Aldersyde," a mansion of large size and elaborate internal appointments, very clearly shows the Norman Shaw influence. The interior is notable, firstly, for a large hall, two storeys in height, which, taken with the staircase (which is placed at one end and divided from it by two rows of arches), measures over fifty feet in length. Lined entirely with oak up to the first-floor level, it forms a noble introduction to a notable house. Dining-room, study, and billiard-room are also treated in oak; the drawing-room finished out in paint, the elaborately-modelled ceiling being one of the two features of this room, the other feature being found in the projecting bay window.

The third phase of Messrs. Penty and Penty's work is chiefly illustrated at present by

MR. ARTHUR J. PENTY.

"Elm Bank," York, a residence conceived and executed in the latest evolution of English art. Modernity in the best sense is the note of it, and it owes its being in this form to the conversion of Mr. Arthur J. Penty to the views of art and decoration familiarised in the theories and in the exhibited works of the Arts and Crafts Society. Messrs. G. Walton and Co., of Glasgow, are here responsible for the painted decorations and the furnishings. Exactly what the interior of this house is like may be judged from the two illustrations we give, of the vestibule and the upper part of the hall, respectively: the first a restful apartment, with a coved and top-lighted ceiling and oak-panelled walls, the door surmounted by a lunette whose generous width recalls the fan-lights of old London houses designed by the Brothers Adam. The upper part of the hall, too, shows how utterly at one with the new school this recent house is.

The work which Messrs. Penty and Penty have of late years been practising in and around York is an indication of the tendencies of modern design. It represents in some degree the possibilities of the Arts and Crafts feeling in architecture. The striving after effect which mars so much modern work is here notably absent. Novelty for its own sake is strictly tabooed. On the contrary, their work tends to

PRIVATE OFFICE AT LENDAL CHAMBERS, YORK. PENTY AND PENTY, ARCHITECTS.

"ALDERSYDE," DRINGHOUSES, YORK, FROM THE SOUTH-EAST. PENTY AND PENTY, ARCHITECTS.

a dignified reserve. Let us hear what they say on Arts and Crafts, and we need no longer doubt to what school they belong. "With reference to this movement, it is our opinion that its influence on modern design must ultimately form the basis of a national style. The return to first principles, which is the kernel of the movement, will have a rejuvenating effect upon architecture. It is a mistake to suppose that the adoption of its creed entails a cutting adrift from the traditions of the past. On the contrary, it will be found that the English vernacular art has for centuries represented the unconscious past of the movement. Its principles may have the air of novelty for the sophisticated modernist who sees everything 'through a glass darkly,' though ultimately they cannot mean anything but sincerity and truth." Which, reduced to its common denominator in the vulgar fractions of everyday doings, is to say that to paint and grain a deal door to resemble oak is an act of original sin, and to paint genuine oak itself (as the ineffable churchwardens of a century ago commonly used to do) is to sin against the light.

Already the streets of York are being noticeably leavened by shop-fronts and restaurants designed by Penty and Penty in this style, the late outcome of modern culture. Let us instance the "Creamery," whose smoke-room we illustrate. This is, of course, hid from the notice of the wayfarer along these ancient streets, who has, however, only to enter that artistically appointed place to discern it. A work of the same class now approaching completion is the Davy Hall Restaurant, a charming design treated with broad effects of restful colours laid on in masses, relieved sparingly with decoratively-carved bosses and panels of birds, beasts, and foliage, in soft wood. Refreshing the inner man in retreats such as this loses all its grossness. An interesting work of redecorating after a fire is the restoration of the interior of Salem Chapel, an uninteresting classical building of the early part of the century.

A newly-finished commission, the Terry Memorial Almshouses form a delightful block, with chimneys rising from the gable-ends in a pleasing battered line, the walls and windows and dedicatory tablet models of proportion and spacing. Indeed, it is largely in the exquisite rightness of the proportions of this later work that much of its charm lies. It is evident, too, in the delightful "Fish and Game Dealer" shop-front, although, to be sure, that has a richness of detail as well. This, it is not too much to say, has set afoot a new era in York. The "Four Alls" inn, on the Malton Road, depending as it does for its charm upon this very exactness and proper inter-relation of parts in the whole, rather than upon any considerations of detail, is a prime instance. A startlingly new departure, too, is seen in the new offices for Messrs. Leetham and Sons, flour millers, the interior being finished simply with green-stained wood doors and desks, the walls left with plainly finished plaster.

Another, and an intensely practical side to this notable firm's doings in architecture, is seen in the Roller Flour Mills for Messrs. Leetham and Sons, a huge pile of red brick, in a style somewhat suggestive of castellation. Constructional and specialist work of this kind has, we understand, been the special work of Mr. Walter G. Penty. To this order belong the extensions to the York Union Workhouse, now in progress, and an electrical laundry in course of erection for the Yorkshire Laundries, Limited. Mr. Walter G. Penty, it should be added, filled the office of President of the York Architectural Society during 1881-2, and again in 1887-8.

Current Periodicals.

The Quarry.—Much space is devoted in the October issue of this publication to the county of Antrim, considered from a geological standpoint, while particulars and illustrations are given (from "Le Génie Civil") of the electric Titan crane to be seen at the Paris Exhibition. This crane consists of a rolling *pylône* (formed by four principal box pillars 10 metres long), which supports on its top a horizontal jib pivoted near its centre and carrying the carriage. It is a very remarkable construction. Attention is also drawn in this issue to the opening of new granite quarries, which has been quite phenomenal during the past year. This is due in some measure to the inadequate supply of suitable stones for monumental and architectural work, but more especially to the unprecedented demand for setts and kerbing for paving purposes. The chief articles in "The Quarry" for November deal with some Yorkshire clay pits and Norwegian national stone quarries.

Sanitary Inspectors' Journal.—"Now that the war in South Africa is practically over, and the authorities are settling down to inaugurate a new government on British Colonial lines, probably nothing is more important than to see that the sanitary laws receive proper attention." This is the opening paragraph of an editorial note in the October number of this journal. The Council has given the matter consideration, and has appointed Mr. J. Dann, M.S.A., late inspector at Poplar, as hon. secretary (*pro tem.*) to take the necessary steps to initiate the South African inspectors in the work, and to establish a branch association in that country.

The R.I.B.A. Journal for October gives a portrait of Professor Lanciani, Royal Gold Medallist, 1900.

The Church Builder.—In the October issue of this quarterly record of the Church Building Society's work there is an interesting illustrated article on the quaint old church of Huddington, seven miles from Worcester and five from Droitwich. The Winters, who settled down at Huddington, are now best known as having added two to the list of gunpowder plotters, but Roger Winter was a great church beautifier and restorer, and he did much for the little building in question. Huddington Church, however, fell sadly into decay, and was so dilapidated that its custodians thought it was past restoration and accordingly applied for a grant to replace it with an iron church. In response to this application £50 was voted by the Worcester Church Extension Society, but fortunately it was never paid, and the building was spared for better things. It is now in the hands of Mr. C. Ford Whitcombe, A.R.I.B.A., but funds are still badly needed. In this number there is also an article on the new Church of Emmanuel in course of erection at Sparkbook (architect, Mr. W. H. Lloyd, Birmingham), and some notes on side altars and side chapels by Mr. J. T. Micklethwaite.

St. George.—This organ of the Ruskin Society of Birmingham publishes Mr. Michael E. Sadler's lecture on school education and preparation. The author points out that "life" is something larger than a means of gaining a livelihood, and he complains that the schools

DINING-ROOM, "ALDERSYDE," DRINGHOUSES, YORK. PENTY AND PENTY, ARCHITECTS.

are too limited, insufficient, and bookish. It is true that during schooldays we learn more from our contemporaries than from our teachers, and more from the example and personality of our teachers than from their set lessons: that the highest function of education is the training of the judgment and the strengthening of the moral will; and while we agree with Mr. Sadler that schools need to be kept in closer touch with life, we think his remarks too general to be of special use. The author says: "Every good school has a personality of its own. It is not a bookstall." We grasp his meaning, but hardly admire the method of expression. The October number of "St. George" contains "An Apology for St. Paul's Cathedral"—some notes of a lecture by Canon Scott Holland (see page 111 of our issue for March 21st last). Mr. J. C. Kenworthy has a short article on "Thoughts of a Recent Visit to Tolstoy," and among other things the number contains a review of the chief articles on Ruskin which have appeared since his death.

The Home Counties Magazine.—Among the articles in the October number of this quarterly are two dealing respectively with the old gate-house of Lincoln's Inn and No. 17 Fleet Street, sometimes called the Inner Temple gate-house; both are concluded from the previous issue. In the former article Mr. W. Paley Baildon deals fully with the old sheds and shops which formerly stood against the east front of Lincoln's Inn gate-house (this objectionable custom was common among our forefathers) and says that probably few passers-by are aware that the predecessor of the old apple woman, who is always seated at her stall on the north side of the arch, followed the same humble calling in the same place more than 350 years ago. In 1885 and 1890 the gate-house was threatened with destruction, but luckily this was averted, and at length, after an interval of nine years, the building has been put in a sound structural condition under the sympathetic guidance of Mr. Dennett Barry, the surveyor to the Inn. With regard to No. 17 Fleet Street, Mr. Philip Norman, after relating the history of the house (it was once occupied by a waxwork exhibition), devotes considerable space to the question whether it was once Nando's famous coffee-house. Timbs says positively that it was, but the author, after much investigation, has grave doubts of the truth of this. Representations of No. 17 Fleet Street in 1786, 1807 and to-day are given.

The Journal of the Society of Architects for October has, as its chief feature, an article by the Rev. William Bazeley, M.A., on the Cistercian Abbey of Hayles, near Winchcombe, in Gloucestershire, which was founded in 1246 by Richard, Earl of Cornwall, brother of Henry the Third. The illustrations, on plate paper, are excellent. This number is the last of the old series; the new series, under the title of "The Architects' Magazine" (see page 257 of last week's issue), will commence next month.

Harper's Monthly Magazine for November contains nothing of special interest to architects.

Feilden's Magazine.—Among the articles in the October issue is Mr. W. N. Twelvetrees' on the Central London Railway. The other articles have little direct interest for our readers.

The **Birmingham Magazine of Arts and Industries.**—No. 6, Vol. 2, is a hospital number, and is descriptive of various hospital institutions in Birmingham. The illustrations reproduce well, but we do not like the paper or the type used in this magazine. The paper is of that very highly glazed variety which is displeasing (and probably injurious) to the eye, while the type is too massive and lacks balance: the headings and the body of the letterpress are quite out of proportion to one another.

The **British Clayworker.**—A writer in the October number deals with the influence of sand in brickmaking. It is very true that much vagueness surrounds the constitution of a "rubber," some defining it as a soft brick used in building gauged work, others as a brick which can be readily disintegrated when rubbed, and the remainder being less sure of the fact and consequently more ready to make exact statements. However, a good rubber has a large proportion of sand, and it is therefore most important that the proper variety should be used. It is useless in the making of bricks to consider the size of the sand grains apart from their mineral nature, as after firing it may be found that the brick has a surface entirely unsuited to its purpose; for a good rubber nothing should be used but a sharp sand, which in some parts of the country is synonymous with a sand containing a good deal of quartz. Other articles in this number are "The Brick-earths of Great Britain: Aylesbury District," "Brick Drying," and "Methods of Expression as applied to Plastic Clay."

THE "TILE HOUSE," YORK. PENTY AND PENTY, ARCHITECTS.

Master Builders' Associations' Journal.—The October number of this journal is devoted almost entirely to the buildings and exhibits at the Paris Exhibition. There are numerous illustrations.

Pall Mall Magazine.—The architect will find more interest in the illustrations than in the letterpress of the article on Dunrobin Castle which appears in the November issue of this magazine: for it is chiefly taken up by an account of the ancient family of Sutherland, which has owned the old castle of Dunrobin in uninterrupted sequence since the days of a somewhat legendary Earl Robin, who raised the original castle on the hill about seven hundred years ago. The gardens of Dunrobin have been beautiful since the days of Princess Margaret. The high lights of some of the illustrations to this article have been largely worked up with a graver, a common practice now with half-tone blocks; and the result is most unsatisfactory, harsh contrasts between line and tone being produced.

The Antiquary for November contains an article on the church of St. Mary Cray, Kent, by J. Russell Larkby, and some quarterly notes on Roman Britain by F. Haverfield, M.A. The church named is at the extreme end of the village and is Early English and Perpendicular, with less than usual of modern restoration. It is externally quite killed by its surroundings—factories and railways.

The Strand Magazine for October contains an article on "Artificial Rock Formation" and "Which is the Finest Building in the World," both of which were dealt with on page 223 of our issue for October 24th.

The Engineering Times prints in its October issue an illustration of the Glasgow Exhibition buildings, now in course of erection. From the Glasgow show of 1888 there was a surplus of £54,000, which, together with interest and private subscriptions, has been increased to £74,000 for the erection of the Fine Art Galleries, which will form the chief architectural feature of next year's exhibition. While the show will suffer to some extent by following close on the heels of those held in Paris and Chicago, the fact that the guarantee fund now approximates £450,000 is an indication of the hearty support the exhibition is receiving. In the number under review, Mr. Brackenbury brings to a close his series of

THE "GREY MARE," CLIFTON, YORK, PENTY AND PENTY, ARCHITECTS.

SMOKE-ROOM AT "THE CREAMERY," YORK. PENTY AND PENTY, ARCHITECTS.

articles on modern methods of saving labour in gasworks, and a new series on "Pumps: their Construction and Management," by Philip R. Björling, is started: it deals with all pumps which can be defined as machines for raising water by the aid of atmospheric pressure, and promises to be interesting.

Architectural Association Notes for November draws attention to Mr. Samuel Gardner's gift to the Association of 200 photographs (each 14½ by 11¼in.) illustrative of the development of English architecture. Such a gift, it need hardly be said, will prove of the greatest value to students, and now that so excellent a start has been made it is to be hoped that the collection will be added to as opportunity offers. Some notes on Wren's London parish churches, by Mr. Percy L. Marks, are also given in this number.

Scientific American (Building Edition).—Since 1891, when Mr. C. B. J. Snyder was appointed Superintendent of School Buildings, a great improvement has been effected in the New York schools, which were formerly conspicuous for their ugliness and mostly built on Italian Renaissance models, consequently suffering from a lack of light. Mr. Snyder obtained a hint for the new H-shaped buildings which have proved so successful from the Hotel Cluny, in Paris; the cost is less per foot than the old schoolhouses of twenty years ago. There is an illustration in the October number of this publication of a very peculiar, though decidedly effective, outdoor music pavilion or bandstand at San Francisco. It was presented by Claus Spreckels, the "Sugar King" of the West, and was designed by Messrs. Reid Brothers, of San Francisco. The pavilion faces a large court surrounded by carriage and bicycle drives and a wide promenade for pedestrians, and consists of a central block with an arched opening 72ft. high at one side, hollowed out behind so as to form an extended half-dome. Here the performers are seated, and the music is projected outwards. At each side of the main block is a double colonnade of Ionic pillars set on a terrace having fourteen steps. The design is severely Classic.

The American Architect.—In the issue for October 6th an attack is made on the newspaper editors who lift up their voices and demand "legislation which, by preventing fires, or reducing the amount of their damage, shall make fire insurance a matter of minor importance." As our contemporary says, this no doubt sounds very eloquent in the ears of the average reader, but it makes the architect smile. It came rather as a shock to find in this issue an article with a headpiece belonging to it, as the "American Architect" has the knack of ignoring these things: for instance in the issue for September 22nd at the head of an article on the excavation of prehistoric Knossos there is a detail from a Paris Exhibition building, and a Montmartre tomb at the beginning of an article on European systems of forest administration. This is hardly observing the laws of fitness. Mr. Brydon's Sessions House design is included among the plates in the issue for October 6th. Mr. Florence's design for the same building is shown in the October 13th number, which also gives reproductions of designs by M.M. Bigot, Bernard and Lemaresquier for "Un Etablissement Thermal." These designs were awarded the Grand Prix de Rome. In going from Padua towards the centre of Italy, the first important city that is met, after Ravenna and Ferrara, is Bologna, where, as it were, the Italian Renaissance breathed its last. An illustrated article on Bolognese architecture appears in the issue of this journal for October 20th. This architecture does not rank very high; it is rather painting which earns for the city its place in the history of Italian art. Among the plates to this issue is one of the third premiated design for the Liverpool Dock Offices (James H. Cook, architect), and another of the Royal School at Honolulu, designed by C. W. Dickey. This latter building has an almost flat roof with wide projecting eaves, and though pleasing in the mass its detail is unsatisfactory in parts, particularly in the treatment above some of the windows.

The Brickbuilder (Boston, Mass.).—"The student of rural domestic architecture must be content to find his pleasure chiefly in the enjoyment of field and woods. The average American farmstead, and its weather-beaten, ramshackle, wooden buildings and unkempt surroundings, adds but a doubtful charm to the landscape." These are the opening remarks of Mr. Robert C. Spencer, junior, in the article which forms the chief feature of the September issue of this journal. The houses of the early settlers in New England, despite their rudeness, were far better than the cheap frame houses which are now being erected all over the United States. These are "just one degree smaller and cheaper and more cheerlessly commonplace than the average mean little house which the speculative builder 'puts up' in the humbler suburbs for poor clerks and working men." The house of the American farmer comes in for less consideration than his barn, and it suffers accordingly. At present the village carpenter is a degenerate, and the plan-merchant holds the field, with a deplorable result. Mr. Spencer, who has made a special study of the subject, says the corrective will be found in placing in the hands of the farm population designs by able men, and in improving the general state of rural education. The designs for farmhouses which illustrate his remarks are pleasing, and we note that the proprietors of the journal take the practical step of instituting a competition for a brick farmhouse, which will undoubtedly take the place of its wooden precursor. The number under review also contains an article on "Practical Fire Tests," being a comparative *résumé* of the tests made by the British Fire Prevention Committee with ceilings, columns, and doors. Facts generally make very dry reading, but this article does not suffer from this fault, and the data it supplies are undoubtedly of much value; not the least useful item is a table showing the fire-resisting qualities of various doors. Of the plates given with this number, that of the Horticultural Hall, Philadelphia (Frank Miles Day and Brother, architects), is certainly the best. The article on practical fire tests is continued in the October number, which also includes an article on the designing and planning of railway stations. Of the plates (which are all excellently printed) that of Cornell University College, New York City (McKim, Mead & White, architects) is the best.

Carpentry and Building (New York).—Some interesting facts as to the relative positions of

UPPER PART OF THE HALL, "ELM BANK," YORK. PENTY AND PENTY, ARCHITECTS.

workmen in Europe and America are supplied in the October issue. The theory that the European mechanic is able to live as comfortably on his smaller wages as his fellow workman in America, because he can obtain necessaries of life more cheaply, does not tally with actual experience. In this country the position of the working population is better than in Continental countries, but it is still materially below that of the American craftsman. "It may be taken as an incontrovertible proposition that the average American artisan enjoys twice the comforts and luxuries of his European contemporary. He has more and better food, is better clothed and possesses more household comforts, and generally has more money saved up for a rainy day." Articles on plumbing without inspection, wood turning, inside window shutters, and a small woodworking shop are given in this number. The brick and frame house shown as a plate is a

which means, of course, a house. *Demo*, in the Greek, means "I build." Viollet-le-Duc points out that the word "dome" is employed for "cupola"; but seeing that the new meaning has become universal, it is useless now to attempt to change it.

Architecture (New York).—It is evident from the statements made by Professor Ware that the Columbia University is striving not only to turn out the theoretical designer, but the practical all-round man as well: one who thoroughly understands the limitations of his art and the complex problems of construction and business which he must face in after life as a practising architect. The day is past when the academically educated man is purely a designer at graduation. Under the heading of "Architectural Practice" are included such subjects as real estate law and the law of contracts. American architecture is now in a state of transition. Architecture to-day, says our con-

a book of nature open and ready, and he has to employ the recorded story of humanity in buildings. Architects will therefore read with great interest the article on architectural books, giving particulars of the Greek, Latin, Mediæval and Renaissance writers, printed in the October number of this publication. The plates presented are of the Symphony Hall at Boston, Mass. (McKim, Mead and White, architects), and the New Chickering Hall in the same city (Peabody and Sterns, architects).

Canadian Architect and Builder.—It is stated in the October issue of this journal that shingled roofs are coming into favour in Toronto, many of them being stained, while others are left to the softening influences of the weather. Some uniform shade of green is the tone most commonly employed, but many architects have successfully mixed their own stains, and thus been able to obtain precisely what tint they desire. Canada, it appears, has no stan-

THE ENTRANCE HALL, "ELM BANK," YORK. PENTY AND PENTY, ARCHITECTS,

hopeless mixture of large rubble work, brickwork and tiles, with the inevitable Classic treatment. For the huge cathedral of St. John the Divine now being erected on Cathedral Heights, New York City, thirty-two granite columns, each 54ft. long, 6ft. in diameter, and weighing about 160 tons, will be required. In the November issue of this journal illustrations are given of one of the enormous square blocks as cut in the quarry and of the special lathe which has been designed to turn them. The corners of the block (which weighs 310 tons in the rough) are first taken off by hand and the stone is then mounted in the great lathe, which has eight cutters, each taking a cut 3in. deep. About six weeks are occupied in dressing and polishing every column. Articles on scissor-trusses, and the heating and ventilating of a club house are given in this issue, and a query is raised as to what is the definition of a dome. The word, like the German term *dom*, comes from the Greek *domos*, through the Latin *domus*,

temporary, is not exclusively an art, and to be successful it must combine economical and commercially successful construction with the greatest amount of beauty possible under the conditions imposed. "If one function of architecture must be sacrificed, the public demand that it shall be its æsthetic side, and although this condition may conflict with our cherished ideas, it is useless for us to attempt to stand in the way of commercial requirements if we are to be abreast of the times." Though deplorable, this is fact. Among the plates presented with this issue are some of the Court House, Appellate Division Supreme Court, in New York (James Brown Lord, architect), and a beautiful country house by Renwick, Aspinwall and Owen. The striped sun-blinds in the windows of the former building, though useful, are incongruous. It is true that no artist is so dependent upon books as the architect; not that he does or should read very much, but he is not furnished like the painter and the sculptor with

dard form of contract. About fifteen years ago a form was agreed upon between the architects and builders of Toronto which was generally used for a considerable time, but, by reason of changing circumstances, many new forms have been introduced, and the need is now felt for a standard contract conserving the rights of all parties concerned. Several papers read before societies are printed in the issue under review, including Professor Beare's on "The Strength of Timber, and How to Test It," read at the Carpenters' Hall. Some particulars are also given of the R.I.B.A. examinations to be held in Canada.

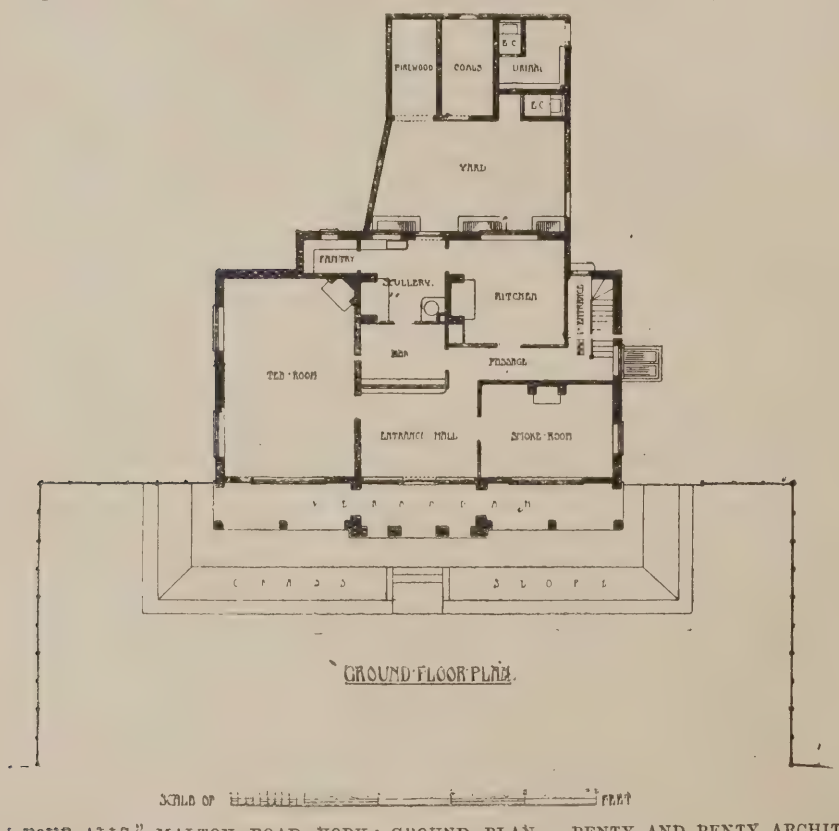
The Building, Engineering and Mining Journal (Sydney, Australia) draws attention in its issue for September 22nd to a Bill which proposes to amend the existing Patent Law by abolishing a searching examination of specifications. This "iniquitous measure" is put forward as the only solution of the problem created by certain high officials who are a bar

to improvement. We quite agree with our contemporary that the only way to secure real protection for patentees and the public is to institute a thorough system of examination; we are badly in need of such a system in this country, and it is to be hoped that some radical improvement will be effected by the Board of Trade Committee, under Sir Edward Fry, which was convened some time ago to examine certain phases of the British Patent Law.

The Clay Worker (Indianapolis).—This publication generally contains much that is readable and of interest, but in the October number we find some very absurd statements. The present is called the steel or the electric age, but we are assured in the issue under review that when Macaulay's Fiji Islander arrives at Trinity Church, New York, to sketch the ruins of Wall Street he will have substantial evidence for calling this the age of terra-cotta. The historians of the future will describe us as copyists, stealing all our lines from the Greeks and the Romans, but will they, asks our contemporary, consider we have improved on the classics? "We are educated now to believe that a good copy is better than a poor original"—what splendid education! And, extending the principle to materials, we find terra-cotta buildings on Broadway masquerading as granite. "Now, presuming it was granite, in what respect would it be better? Only one possible known reason: it would have cost more." Such is our contemporary's view, and what a wretched one it is. Any material can be built, but why, if terra-cotta is chosen, try to make it look like granite? It is like a man habitually wearing a false moustache, and about as commendable.

Die Kunst.—In the November issue there is an article dealing with the work of Messrs. Schilling and Gräbner in Dresden. These architects may be taken as fairly representative of the new art movement so strong in Germany at the present time. We have already pointed out the excesses which are made, with results wholly absurd and hideous, but those who are unacquainted with the movement should endeavour to see some examples of it, as it is interesting in many of its aspects. Its great fault is the production of something novel simply for the sake of novelty, irrespective of the considerations of beauty and fitness.

Berliner Architekturwelt.—The remarks made in connection with "Die Kunst" apply even more pertinently to this publication, which has some most curious designs for bridges and buildings in the current issue.



BRITISH SCHOOL AT ATHENS.

ON Tuesday in last week the annual meeting of subscribers to the British School at Athens was held at Burlington House, Mr. H. Asquith, M.P., presiding.

In the course of their report for the session 1899-1900, which was read by Mr. George A. Macmillan, the managing committee said:—Although the number of students has been less than in some previous years, the work of the school, under the direction in Crete of the director of the school, Mr. Hogarth, and in Athens of the assistant-director, Mr. Bosanquet, has been profitably carried on. Of the four new students one is Mr. D. Theodore Fyfe, who was appointed by the committee to the architectural studentship. Mr. Fyfe has done admirable work in Crete, where he not only made the plans and surveys which lay within his special province, but also showed marked artistic talent in his water-colour drawings of the frescoes found by Mr. Evans.

The only excavations undertaken by the school this session were those in Crete. Mr. Hogarth has worked with great success on the site of the town of Knossos, and later in the cave at Psychro which has been hitherto identified, as it now appears with reason, with the far-famed Dictæan Cave. St. Luke's Monastery at Stiris in Phocis, which represents the first instalment of the valuable studies on Byzantine architecture in Greece made some years ago by two students of the school, Mr. R. W. Schultz and Mr. Sidney Barnsley, will shortly be published by Messrs. Macmillan and Co. The cost of the plates has been met by a generous contribution from one of the trustees of the school, Dr. Edwin Freshfield. In this connection it is only fitting to mention the serious loss sustained by the school generally, and by the Byzantine side of its work in particular, through the recent death of the Marquis of Bute, who more than once made liberal contributions to the Byzantine Architecture Fund.

In last year's report reference was made to a project for establishing a British school at Rome. Considerable progress was made in drafting a scheme for such a school, and an attempt was made privately to raise funds to enable it to be started this autumn on however small a scale, but the effort has met with only limited success. In spite of this discouragement a very competent director has been provisionally appointed in the person of Mr. Gordon Rushforth, of Oriel College, Oxford, who knows Rome thoroughly and has shown expert knowledge alike in the field of Latin epigraphy and of Italian art.

GROUND-FLOOR PLAN.

Correspondence.

"Severn End."

To the Editor of THE BUILDERS' JOURNAL.

WORCESTER.

SIR,—On page 203 of your issue for October 17th it is stated that "Severn End," the ancient residence of Sir Edmund Lechmere, Bart, was burned down in October 1896, together with its ancient furniture, pictures, manuscripts, and books. The inference to be drawn from the paragraph is that the house no longer exists. We desire to state that the house was only partly destroyed, and nearly all the ancient furniture, pictures, manuscripts, and books of value were saved. The house has been most satisfactorily restored, and retains its ancient character and detail, and Sir Edmund is now in residence there.—Yours truly,

LEWIS SHEPPARD AND SON.

Builders' Notes.

Of the 3,000 odd candidates for the new London Borough Councils there were 140 builders and contractors.

Partnership Dissolved.—The partnership subsisting between Messrs. John Turner Taylor and Frederick Taylor, carrying on business as builders, joiners, and cabinet makers, has been dissolved by mutual consent as and from October 24th. All debts due to and owing by the late firm will be received and paid by Mr. John Turner Taylor.

Mr. John Nicol Dunn, senior partner of Messrs. Dunn Brothers, stonecutters and granite merchants, of Holland Street, Aberdeen, died last week at the age of 54 years. He served his apprenticeship as a stonecutter with Messrs. Macdonald, Field & Co., and afterwards was associated as a partner in the firm of Messrs. Dunn & Mitchell, stonecutters. About twelve years ago, he and his brother formed a partnership under the firm name of Messrs. Dunn Brothers, and carried on an extensive and successful business.

Building in Edinburgh.—During the past year, not only owing to the masons' strike, but owing to the large amount of building during previous years, fewer new buildings were constructed than formerly. A large number of alterations and additions, however, are constantly taking place on the buildings of the city. During the year in the Dean of Guild Court 969 warrants were granted; but of these 42 were minor warrants for small alterations and did not require the full petition. There were 12 new villas and self-contained houses, and 81 tenements; of the latter, 50 were houses of one apartment, 515 of two apartments, 338 of three, 70 of four, 17 of five, and 3 of six apartments, making a total of 993 houses and 47 new shops, 43 villas, 85 self-contained houses, 227 public and other buildings, and 257 alterations.

London County Council.—At last week's meeting of the Council a proposal to construct a winter garden in connection with the London Hippodrome was adopted after some discussion. The Public Health Committee recommended "That a letter be addressed to the Local Government Board stating that the Council is of opinion that the Sanitary Officers (London) Order, 1891, should be amended so as to enable sanitary authorities to appoint female sanitary inspectors, the whole or part of whose duties would be the teaching of habits of cleanliness and of the best methods of utilising food; and that the Council do express its willingness to contribute a moiety of the salary of every female sanitary inspector so employed." The recommendation was temporarily withdrawn. The Council adopted a series of new by-laws relating to drainage.

Bricks and Mortar.

APHORISM FOR THE WEEK.

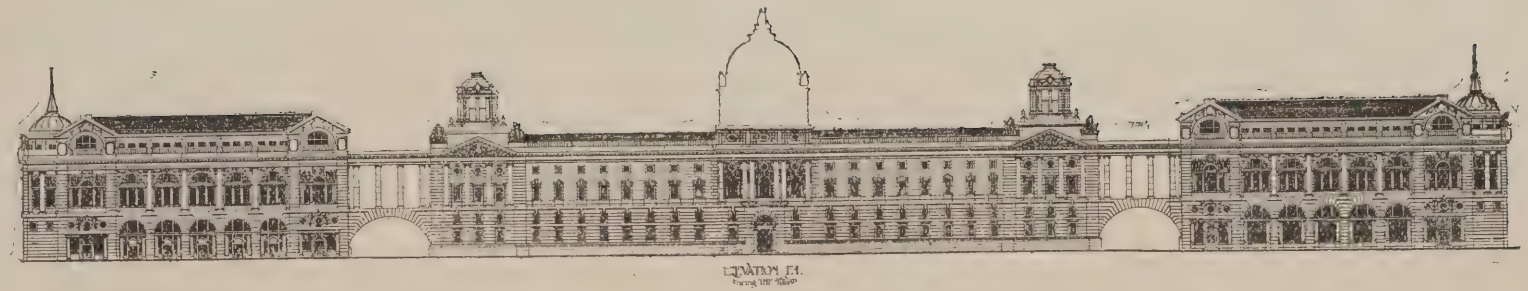
If you have understood anything I ever told you about Gothic, you know that no architecture was ever corrupted more miserably or abolished more justly by the accomplishment of its own follies. RUSKIN.

Our Plates. A CRITICISM of the designs for the Holborn-Strand street was published in our issue for last week. The illustrations of the "Four Alls" inn and the fish and game dealer's shop at York are referred to in the article on the work of Messrs. Penty and Penty which commences on page 268 of this issue

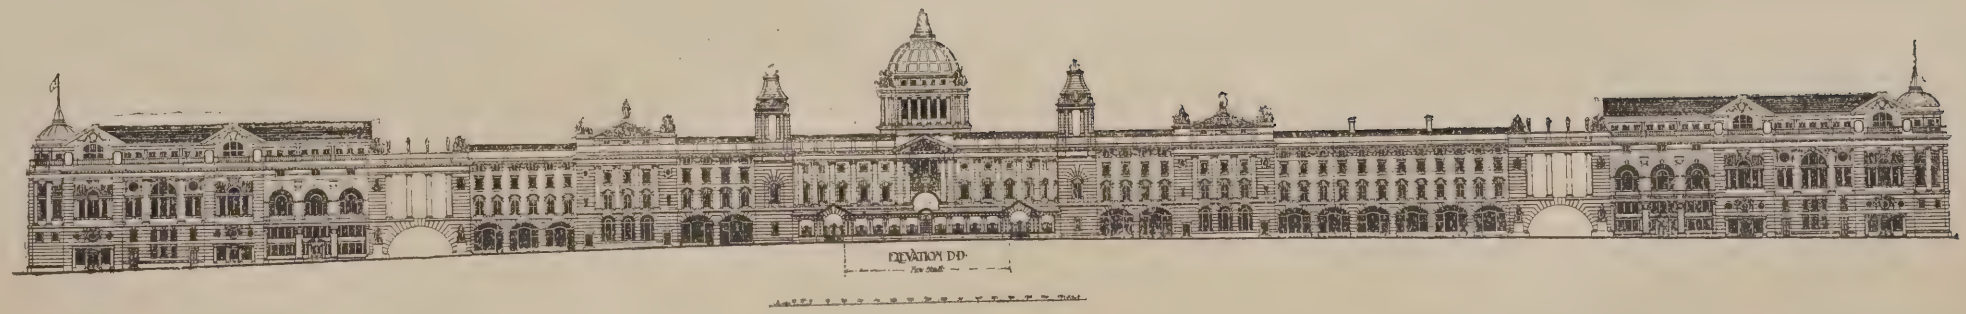
The New Bridge at Kew. A MASSIVE granite shield surrounded by scroll work has been completed in the yard of Mr. John Fyfe, granite merchant, Provost Blaikie's Quay, for the three-arched granite bridge which is at present being constructed over the Thames at Kew, under the superintendence of Mr. Easton Gibb. The shield is 10ft. high and 17ft. wide. Above it there is an allegorical head representing Old Father Thames, and on its face have been carved the coats-of-arms of the three principal towns of Surrey. The bridge, it may be explained, is being constructed at the expense of the counties of Middlesex and Surrey, each of which bears half of the cost, and as the shield executed by Mr. Fyfe is for the adornment of the Surrey end, the coats-of-arms of the principal towns in that county have been represented on it. The shield is being duplicated, and the two duplicates will be placed on the spandrels of the Surrey arch, above the pier. It is of fine axed Kemnay granite, and the ornamentation is in bold relief.

An Art Colony. THE scheme of the late Mr. Patrick Allan Fraser to establish an art colony in Hospitalfield, Arbroath, is about to be completed, and with this object in view Mr. George Harcourt, assistant to Professor Herkomer, at Bushey, has been appointed master at a salary of £400 per annum with free house. Mr. Fraser, on his death in 1887, left his residence near Arbroath—supposed to be the Monkbarns of "The Antiquary"—together with a sum of money for endowment purposes in the hands of trustees with a view to founding an establishment of this kind, but it was decided to let the matter lie in abeyance for a time. The scheme is for the encouragement of young men having insufficient means of their own who are desirous of following out one or more of the professions of painting, sculpture, carving in wood, and engraving. For the carrying out of the scheme it is provided that 30 young men shall be comfortably lodged, boarded, and clothed in the house of Hospitalfield. The age of the applicants for admission must not be less than 16, nor more than 18. The students admitted are to be entered for a period of four years. Students are also to be provided with summer quarters at Blackcraig or Glenrinnes, in Perthshire, while allowance has been made for students who have completed their indentures at Hospitalfield going to the Continent to complete their education as artists. In addition to the regular students, young people resident in Arbroath between the ages of 16 and 20 may also be received.

A Collection of Glasgow Architectural Photographs. THE R.I.B.A. having agreed to the proposal made by the Glasgow Institute of Architects that their 1901 dinner should be held in Glasgow during the time the Exhibition is open, a Committee has been appointed to make arrangements for the reception of the Royal Institute during the Exhibition. The date proposed is early in October, but the Committee are at present in communication with the Corporation on the subject. It has been arranged to exhibit a collection of photographs illustrative of the architecture of Glasgow, from the earliest times till the present day. The photographs, to the number of about 150, will be provided by the Glasgow Institute, and will revert to it after the close of the Exhibition, to form a permanent feature of its library collection, which will, it is hoped, be enriched from year to year by contributions of photographs of current representative works by members and others. While the Institute has voted from its Capital Fund sufficient to proceed meantime with the collection, where the work is by architects unknown or long deceased, it has, in connection with work of more recent date invited, and in most cases obtained, the co operation of many existing firms in procuring photographs of works by retired or deceased architects still represented by them. The list of works to be illustrated was drawn up by a sub-committee appointed for this purpose, and approved by the Council. The Committee has also been instructed to co-operate as far as possible with the Exhibition Fine Art Committee towards securing, in the contributions of local architects to the section of modern architecture, some continuity with the retrospective collection.



New Furniture Museum at the Louvre. THE Louvre is to be enriched by transferring to it the cream of the treasures hitherto preserved, and very badly preserved, at the Garde-Meuble. This latter institution is the repository in which the State stores the old furniture, the Gobelins tapestries, the Sèvres ware, and other kindred objects of which it is the possessor. The Garde-Meuble is not open to the public, so that its most interesting contents, which, of course, are national property, are in some sort sequestrated. What is worse, they are exposed to grave dangers. It has been proved again and again that the treasures of the Garde-Meuble are in very careless custody. A well-known art critic discovered a series of Gobelins which the ignorant and indifferent employees had rolled up with no more care than if they had been second-hand carpets. But besides being housed in deplorable conditions, the contents of the Garde-Meuble are the prey of privileged pillagers and pilferers. The Ministers have the right to draw on the Garde-Meuble for the adornment of their official residences. The Garde-Meuble has even been rifled for the benefit of colonial functionaries anxious to impress the barbarian mind at the expense of the art treasures of the metropolis. The natural consequence of these many borrowings is considerable "leakage"; not everything that leaves the Garde-Meuble returns to it in due course. There is to be an end to this state of things. All the finest specimens in peril of their existence in the Garde-Meuble are to find a safe refuge in the Louvre. The immense success of the retrospective furniture exhibition in the Petit Palais has been the decisive argument that has enabled the innovators to carry the day. Five spacious rooms on the first floor of the Louvre are to be reserved for the new department. They have already been emptied of the drawings they previously contained and are now in the hands of the painters and decorators, of whose good offices they stood in sad need, as they had never been repaired since the Restoration. The periods represented, to begin with, will be the sixteenth and seventeenth centuries.



The Roman Forum. THE Rome correspondent of the "Morning Post" writes: "The excavations in the Roman Forum, which under the direction of Signor Boni have led to the discovery of so many interesting pages of early Roman history, are beginning to excite a lively interest among the Italians, and particularly among the people of Rome. Until recently the Forum was regarded by the general Italian public as a special preserve for the erudite, in which ordinary people could not be expected to take an interest. But when the Black Stone, the Sacred Way, the Altar of Mars, the pavements of the house of the Vestals, the Palatine Basilica with its magnificent paintings, the Rostrum from which Mark Antony harangued the Roman crowd, and especially the poetic fountain and well of the nymph Juturna were brought to light the Roman populace of to-day began to feel that it had a sort of special property and a living interest in all these relics of the past, of which it had only known before in the form of legend and tradition. This feeling immediately revealed itself when it was rumoured that the present Minister of Public Instruction, Signor Gallo, meant to suspend the excavations for want of funds. An outcry at once arose, and the idea of a national subscription for the continuation of the work in the Forum was put forward. Without waiting for the opening of the subscription a young engineer officer sent 1,000 lire as his contribution, and the press of all parties has praised his example and is urging all Italians who have the means to imitate him. This movement is an excellent sign of an improvement in the condition of Italian public opinion, which at last seems to be waking up to the fact that it can do much without waiting for the initiative of the Government."

The late Mr. William Anderson. The death of Mr. William Anderson, F.R.C.S., occurred recently at the age of 58 years. The deceased was elected Professor of Anatomy to the Royal Academy of Arts in 1891. He lived for some years in Japan, which enabled him to attain a good knowledge of the decorative and pictorial art of the Japanese, and to form the valuable collection of Japanese and Chinese books, pictures, drawings, and wood engravings now in the British Museum. Besides being the editor of "Heath's Practical Anatomy" and "Brücke's Beauties and Defects of the Human Figure," he was the author of "Deformities of the Fingers and Toes," "The Pictorial Arts of Japan," and "Japanese Wood Engravings" (portfolio monograph).

Manchester Corn Exchange. THE new roof of the Manchester Corn Exchange, which is to be finished by March next, is nearly complete so far as its skeleton is concerned, half a dozen iron girders, weighing four tons each, having been successfully hoisted into their places. The result of the enlargement, which commenced so far back as 1891, will be to turn the Corn Exchange from its polygonical shape into a triangle, having for its three sides, Hanging Ditch, Fennel Street and Cathedral Street. The first-named street has been already widened to 18yds., and will be further improved by the new Corporation and Market Street scheme now being considered by the Corporation Committee. It is interesting to note that the present building dates from 1837—the date of the Queen's accession. Before that time corn exchange business was transacted in the open air, and there still exists an old bell on the Fennel Street side of the Douglas Hotel which was used to summon the farmers and traders to mid-day dinner.

Holborn-Strand Designs. REFERRING to these designs the *Daily Chronicle* says:—"If the result of the recent architectural competition for the new Strand is to be a composite design, embodying what the County Council think the best features of the best drawings, then £2,000 of the ratepayers' money has been thrown away. None of the plans may have been, architecturally, a masterpiece, but there was a point upon which all the competitors agreed: that is, in respecting the unity of the group of buildings destined to fill one of the most important sites in commercial London. Everybody knew beforehand the difficulties of carrying out any such unity. Either ratepayers had to be boldly faced and the Council become proprietors of the entire group, or else each tenant had to be compelled to build under the Council's supervision. But if the Council were not prepared to grapple with these difficulties, to what purpose the competion and its attendant expenses? The new street and the new Strand might as well have been left to the same haphazard that has made such nondescript thoroughfares of Charing Cross Road and Shaftesbury Avenue. Indeed, the new buildings will seem all the worse for the hint revealed here and there of a definite architectural scheme."

THE HOLBORN TO STRAND THOROUGHFARE. Design No. 26.

EXPLORATION IN CRETE.

WONDERFUL DISCOVERIES.

THE following particulars of the Cretan explorations were given to the Press last week by the well-known archæologists Mr. A. J. Evans and Mr. D. G. Hogarth:—

The preoccupation of the public mind caused by the war in South Africa made it impossible last year to press the claims of Cretan exploration. Sympathy, indeed, was not wanting. A representative committee was formed, and we were able to initiate a fund, to which the patronage of the High Commissioner of the Powers in Crete, Prince George of Greece, was graciously accorded. Thanks to the good offices of his Royal Highness, a number of important sites were set apart for British excavation. But of the £5,000 required for the adequate realisation of our scheme barely a tenth part was collected by private subscriptions.

Meanwhile Italian and French missions, supported by Government aid, had already been in the field for several months. Even to hold their own it was absolutely imperative that British representatives should make a beginning. We had no choice but to embark last spring on an enterprise which, once begun, for the honour of British science must be carried through.

The sum of less than £500 that had been privately collected was devoted to the assistance of two separate enterprises. Half of the amount went to assist one of the above-named gentlemen in the excavation of a site, already acquired by him at Kephala on the site of Knossos, which proved to contain the remains of a prehistoric palace. How inadequate was this contribution may be judged from the fact that five-sixths of the cost of the work—still far from completion—have fallen on the explorer's shoulders. The other half of the sum collected was allocated to the director of the British School at Athens for the exploration of the prehistoric town and tombs of Knossos and of the great cave of Zeus, on Mount Dicta. This was supplemented by £200, spared with difficulty from the annual income of the school, and by the payment of an architect from the same source. The extraordinary results which rewarded both these undertakings have attracted such wide attention that a very brief statement will suffice here.

The Discoveries made at Knossos

throw into the shade all the other exploratory campaigns of last season in the Eastern Mediterranean, by whatever nationality conducted. It is not too much to say that the materials already gathered have revolutionised our knowledge of prehistoric Greece, and that to find even an approach to the results obtained we must go back to Schliemann's great discovery of the Royal tombs at Mycenae.

The prehistoric site, of which about two acres have now been uncovered at Knossos, proves to contain a palace beside which those of Tiryns and Mycenae sink into insignificance. By an unhoped-for piece of good fortune the site, though in the immediate neighbourhood of the greatest civic centres of the island in ancient, medieval, and modern times, had remained practically untouched for over 3,000 years. At but a very slight depth below the surface of the ground the spade has uncovered great courts and corridors, propylaea, a long succession of magazines containing gigantic stone jars that might have hidden the Forty Thieves, and a multiplicity of chambers, pre-eminent among which is the actual throne-room and council-chamber of Homeric kings. The throne itself, on which (if so much faith be permitted to us) Minos may have declared the law, is carved out of alabaster, once brilliant with coloured designs and relieved with curious tracery and crocketed arcading which is wholly unique in ancient art, and exhibits a strange anticipation of thirteenth-century Gothic.

Frescoes, Paintings, and Sculpture.

In the throne room, the western entrance gallery, and elsewhere, partly still adhering to the walls, partly in detached pieces on the floors, was a series of fresco paintings, excelling any known examples of the art in Mycenaean Greece. A beautiful life-size painting of a youth, with a European and almost classically Greek profile, gives us the first real knowledge of the race who produced this mysterious early civilisation. Other frescoes introduce us to a lively and hitherto unknown miniature style, representing, among other subjects, groups of women engaged in animated conversation in the courts and on the balconies of the palace. The monuments of the sculptor's art are equally striking. It may be sufficient to mention here a marble fountain in the shape of a lioness's head with enamelled eyes, fragments of a frieze with beautifully-cut rosettes, superior in its kind to anything known from Mycenae; an alabaster vase naturalistically copied from a Triton shell; a porphyry lamp with graceful foliation supported on an Egyptianising lotus column. The head and parts of the body of a magnificent painted relief of a bull in *gesso duro* are unsurpassed for vitality and strength.

It is impossible here to refer more than incidentally to the new evidence of intercourse between Crete and Egypt at a very remote period supplied by the palace finds of Knossos. It may be mentioned, however, as showing the extreme antiquity of the earlier elements of the building that in the great eastern court was found an Egyptian seated figure of diorite, broken above, which can be approximately dated about 2000 B.C. Below this again extends a vast Stone Age settlement which forms a deposit in some places 24ft. in thickness. Neither is it possible here to dwell on the new indications supplied by some of the discoveries in the

"House of Minos"

as to the cult and religious beliefs of its occupants. It must be sufficient to observe that one of the miniature frescoes found represents the façade of a Mycenaean shrine, and that the palace itself seems to have been a sanctuary of the Cretan God of the Double Axe, as well as a dwelling-place of prehistoric kings. There can be little remaining doubt that this huge building with its maze of corridors and tortuous passages, its medley of small chambers, its long succession of magazines with their blind endings, was in fact the Labyrinth of later tradition which supplied a local habitation for the Minotaur of grisly fame. The great figures of bulls in fresco and relief that adorned the walls, the harem scenes of some of the frescoes, the corner stones and pillars marked with the *labrys* or double axe—the emblem of the Cretan Zeus, explaining the derivation of the name "Labyrinth" itself—are so many details which all conspire to bear out this identification. In the palace-shrine of Knossos there stands at last revealed to us the spacious structure which the skill of Daedalus is said to have imitated from the great Egyptian building on the shore of Lake Moeris, and with it some part at least of his fabled masterpieces still clinging to the walls.

But, brilliant as are the illustrations thus recovered of the high early civilisation of the City of Minos and of the substantial truth of early tradition, they are almost thrown into the shade by a discovery which carries back the existence of written documents in the Hellenic lands some seven centuries beyond the first known monuments of the historic Greek writing. The problems attaching to the decipherment of the clay records which had been found are of enthralling interest, and we have here locked up for us materials which may some day enlarge the bounds of history.

The work of excavation in the Palace of Knossos is barely half completed, and yet whichever way we turn the relics already obtained from within its walls supply new and unhoped-for *data* for the reconstruction of early Ægean civilisation. Nor is this all. Exploratory digging to the south and west of the palace revealed a veritable Pompeii of houses of the same early period, which yielded, among other things, by far the finest series yet found of vases of the singular primitive Cretan polychrome style, unrepresented in European museums. One remarkably well-preserved block of buildings appears to be a group of shrines devoted to a pillar worship, such as is known on the Phœnician and Palestinian coasts, and of which the palace itself supplies an example connected with the cult of the Cretan Zeus.

Finally, in the early heats, the clearing of the Cave of Psychro, notorious since some years for its rich votive deposits, was carried out. This cave is no other than the holy Dictaean Cavern, in which Hesiod and Virgil state that the Supreme God was cradled. The discoveries of vases, weapons and other articles made in this cave cover the whole primitive period of Cretan history back to the pre-Mycenaean epoch.

The Work Still to be Done.

The clouds of war are at last lifting, and it is with confidence that we now appeal for help to carry on the work already set in hand. The Palace of Knossos is still but half uncovered, and the large expenditure entailed by excavation of this vast building, which its explorer hopes to take up again in February next, is a severe strain on individual resources. Among the other sites included in the British concession are two votive caves, the citadels of more than one Mycenaean city of eastern Crete, and Praesos, the ancient capital of that region, within whose walls the language of the old indigenous stock—the Eteokretes of the Odyssey—survived to historic times. Here, if anywhere, should be found the key to the undeciphered hieroglyphic script of Crete, and it is to be hoped that sufficient funds may be forthcoming to begin excavation at this spot during the coming season under the auspices of the British School of Athens. The Cretan Exploration Fund needs contributions to the amount of at least £3,000.

Subscriptions may be paid either to Mr. George Macmillan (as hon. treasurer) at St. Martin's Street, London, W.C., or into the account of "The Cretan Exploration Fund," at Messrs. Robarts, Lubbock & Co.'s., Lombard Street, E.C.

Surveying and Sanitary Notes.

New Destructors for Bradford.—Having received and carried out orders for two destructors for the city of Bradford, the Horsfall Destructor Company, Ltd., have just secured contracts from the same city for five more plants to serve fresh districts.

Street Improvements at Halifax.—The Corporation have purchased the shop and premises at the Pellon Lane corner of Back Street for £300, to enable Pellon Lane to be widened. They have also acquired offices, store-rooms, and shop in Pellon Lane, the purchase price of these, with 112yds. of land, being £2,750. It has been definitely decided, with the approval and consent of Mr. W. Swindon Barber, to remove the statue of the late Colonel Akroyd from its position at North Bridge to the site below All Souls' Church.

New Buildings for the Newbiggin and District Co-operative Society, Limited, were recently opened at Seaton Hirst. The buildings occupy a commanding position, and cover about 750 square yards. They are faced with Penshaw pressed bricks and stone dressings. On the ground floor are the grocery department, butchery department, greengrocers' shop, bootmaking department, and a large warehouse which has a covered-in dock, so that carts can be loaded or unloaded under cover. In the rear of the building is a good three-stalled stable, harness-room, and other offices. On the first floor is a large drapery department, principally lighted from the roof, by Helliwell's patent glazing, also several other rooms for conducting business. The lighting is by acetylene gas, and the heating by hot-water radiators. The whole of the work has been carried out by Mr. Beattie, contractor, of Pegswood Quarry, from plans and under the superintendence of Messrs. Boolds and Hardy, architects, Morpeth, and Newgate Street, Newcastle-on-Tyne.

R. I. B. A.

President's Opening Address.

ON Monday evening last the Royal Institute of British Architects held its opening meeting of the session 1900-1901. The President, Mr. William Emerson, expressed deep regret at the loss they had sustained by the death of Mr. William Young. He had a large practice in the country, had erected many houses for the nobility, and was one of the two architects selected to design the new Government offices. It was decided that a vote of condolence should be sent to Mr. Young's family and relatives. Mr. Alexander Graham announced with regret the death of Mr. Joseph Goddard, of Leicester, who was elected a Fellow in 1871, and of Mr. Charles H. Driver, who was elected a Fellow in 1872. The death of Mr. Lloyd Tayler, of Sydney, Australia, was also announced.

The Secretary (Mr. W. J. Locke) stated that Mr. H. Legg (Christ's Hospital) and Mr. R. D. Hanson (Dulwich, S.E.) had passed the statutory examination held on October 25th, and had been granted certificates of competency to act as district surveyors under the London Building Act.

Mr. Aston Webb then presented to the Institute a portrait of the past-president, Professor Aitchison, painted by Sir Lawrence Alma-Tadema. He referred to the excellent work done by Professor Aitchison, his ability as an architect, his eminence as a scholar, and his geniality as a friend. The portrait would be a worthy addition to those already hung on the walls—the late John Whichcord, by Tadema himself; the late Professor Cockerell, by the late J. Boxall; the late Sir Horace Jones, by the late Frank Holl; Alfred Waterhouse, by Orchardson; and F. C. Penrose, by Sargent. In acknowledging the gift the President expressed the thanks of the Institute to the painter for thus placing his genius at their disposal, and he moved that a vote of thanks be given to him.

Sir Alma-Tadema, in replying, said that it gave him the greatest pleasure to paint the portrait, for what could be more pleasing to the artist than to paint a portrait of a dear friend for a dear friend—the Royal Institute of British Architects.

The President then delivered his opening address as follows:—

On taking this chair at our first sessional meeting of the twentieth century, the sixty-sixth in our annals as a Chartered Institution, I find it difficult to express in suitable terms my high appreciation of the honour of being again elected to the office of President. I can only say it shall be my most earnest endeavour to advance the interest, promote the welfare, and enhance the influence of the Royal Institute of British Architects, and to uphold the dignity of the profession.

Let us consider some few points of interest in connection with the architectural practice of the present time, as well as some subjects of importance that may influence our art during the twentieth century.

Architectural Education.

There can be no doubt that the most important question of the moment is the necessity for a better and more methodical system of education for our students in architecture than exists at present. The Institute can only stimulate and assist such steps as may be taken in this direction. Its *rôle* is not that of a teaching society; its function is to foster and encourage the art of architecture, to guard the interests of the profession, and to examine and ascertain the qualifications of those wishing to be enrolled on the list of its members. England is lamentably deficient in adequate means of imparting the necessary grounding to the students who wish to turn their attention to this particular art.

More severe and systematic courses of tuition exist in France. Their devotion, however, is limited almost exclusively to Renaissance. Their work, often most correct, is somewhat wearisome. But their course of study is thorough. A close familiarity with the best of what has gone before in Classic, Gothic, and other styles should enable the architect who is gifted with some power and freedom of thought and expression to avoid the wearisomeness of modern French architecture. And it may be remarked in passing that the faults in proportion and detail, and the incongruities often found in our English work, might be avoided in like manner. The new Byzantine Cathedral of Marseilles shows the thoroughness of French methods of study.

In France the centre of this thorough study of architecture, where each student gets properly grounded in first principles, is the Ecole Nationale des Beaux-Arts. And this is a Government establishment. In Italy the central school is the Academy of St. Luke, also under Government. In Germany there are a number of excellent training schools for architects, all under Government control.

In the universities, colleges, and technical institutes of America there are about half a dozen or more first-class training departments in architecture, which have now reached such efficiency that their students are ceasing to go to France for purposes of study. And the best American architects are often university graduates to begin with. All these countries have felt that the interests of the community and the State demand the efficient education of the student of architecture.

In England at present there are no Government schools of architecture worthy of the name, or any individual endowments that would render a successful organisation possible. It is true there have been certain schools of architecture attached to the schools of art, as at South Kensington; but in these the grounding in first principles has been on somewhat unsystematic and desultory lines, and the teaching of architecture is altogether subservient to the classes for painting and sculpture. The methods at the Royal Academy School appear to be similarly wanting in systematic grounding. A new school, under the Board of Education, forming part of the Royal College of Art, has been inaugurated at South Kensington, and a reorganisation of the schools of art generally is in progress; but this new school is, apparently, to be of limited scope, and designed mainly for the training of art teachers; and though students of architecture will be received, it will be chiefly to learn drawing and the artistic side of architecture. It will, therefore, be a hard task for the new teaching authorities to make it a complete and systematic school of architecture from the foundation to the finish. However, until it starts work, it is premature to say what it may become or to discuss its efficiency.

Our universities seem to ignore architecture—the only bodies who touch the subject at all being University College and King's College, London, and Victoria University in the North.

It had been hoped that the authorities, in the reconstruction of the London University, would have taken some steps for the representation of architecture; but, notwithstanding that their attention had been particularly drawn to the desirability of this, architecture remains unrecognised, and can only now be admitted by Act of Parliament. Apparently this is because there are really no properly-constituted or efficient schools of architecture in the country, or none worthy of university recognition. However, Mr. Bailey Saunders, the Secretary to the London University Commission, in his letter to the "Times," informs us "that amongst certain Boards enumerated in the regulations a Board of Fine Art, including architecture, is to be appointed, and that there is nothing to prevent the future Senate recognising architecture as a branch of science." Let us hope it may also be recognised as a Fine Art.

Our junior society, the Architectural Association, has done much in the matter of architectural education. If it extends its work in the direction suggested by the President a short time back, and becomes really a teaching body, a properly constituted, systematic and efficient school of architecture such as the universities will recognise, the thanks of the whole profession will be due to it, and an advance of unparalleled significance will have been made in our architectural education.

In connection with education we have in the collection of casts that forms the Architectural Museum a most potent instrument ready-made to our hands. If this Museum, expanded in scope, were made part of the school suggested by the Architectural Association, and were organised in connection with the Institute, it would be of great use to students and practising architects.

Architects' Registration.

A second very important question is that of the present status of the architect. Any person, however unfitted to practise the art of architecture, or even that of building, with no pretence of architecture at all, can put a plate on his door and dub himself "architect." This is an absurdity, and as much a danger to the lives and pockets of the community as the quack practising in medicine. With a view to remedying this state of affairs it has been suggested that some form of registration by Act of Parliament of architects now carrying on business (and hereafter those who have passed an examination) should be adopted. But as this would not prevent quantity surveyors, engineers, land agents, house agents, builders, and others undertaking the duties of architects, and obviously for many years would introduce to the public a host of absolutely unqualified men. I need scarcely remind you that the Institute has hitherto strenuously opposed such a measure. That the public should be safeguarded in some way in regard to the practice of architecture by unqualified persons is becoming daily more apparent.

A revival of the ancient guild system seems to be a strongly marked modern tendency; nor can there be any doubt of its protective value to all professions, since enrolment in a recognised society practically amounts to registration. Thus, accountants are not, I believe, bound by Act of Parliament to register; but no one can use the title "Chartered Accountant" unless he belongs to the Institute of Chartered Accountants and has passed an examination.

The Incorporated Law Society commenced its existence in a very similar way to the Royal Institute of British Architects. After a time it began to impose the passing of examinations as a condition of membership. Later, the registration of solicitors was made compulsory. Still later they acquired the entire control of examinations, the custody of the Roll of Solicitors, the registration of articles of clerkship, the power of admission and readmission of solicitors, the renewal of their certificates, and other powers. To follow on somewhat similar lines should be our policy.

Public Competitions.

There is a third matter, in relation to architects and the practice of architecture, to which I must refer, and that is public competition. This was a burning question when I was a pupil, is a burning question now, and will, I fear, continue to vex the souls of future architects. I cannot help expressing the opinion, based on years of experience, that, whether looked at from the point of view of the client who desires to obtain a good building, or of the architect who wishes to do himself justice, or of the general public interested in fine architecture, architectural competitions are a failure. In most cases better designs, or designs more suited to special requirements, would result if architect and client were in constant consultation from start to finish than if the former were working from printed instructions only.

In making these remarks I have no wish to decry the work of many of those eminent architects who have earned their reputations by competition. In my own case the commission for the largest building I am responsible for—the Allahabad University for the Government of India—was obtained in competition. But I am bound to say it was practically redesigned, in consultation with the authorities concerned, after the competition had been decided in my favour.

It is said, however, that the competition gives the young man a chance. That may be so; but in architecture, as in every other profession, the man of energy and ability will come to the front, competition or no competition. The work a man has done is as good a criterion of his powers as any fresh design he may produce in

competition, and it becomes simply a cruel waste of time and money to force him continually to compete.

In a merely economic sense the waste of money and energy in this strife is absurd and monstrous. In six competitions I could name the total sum to be expended was £400,000, and there was an aggregate of 320 competitors. Say that each one spent at least £60—which in most instances is less than the actual sum—on the preparation of the plans, the total cost to the architectural profession in competing for these six works would have been £19,000, and that for a nett profit to be divided amongst the six successful architects of about £12,000; assuming that, say, 2 per cent. on the total amount involved would be the cost to the architects of carrying out the works.

There is one other matter I may mention in connection with our professional practice. After negotiations lasting I am afraid to say how many years, at last a definite form of Building Contract has been agreed upon between our Council and the Institute of Builders, and now only needs the approval of our general body at a business meeting. This will save endless difficulties between architects and their clients and contractors in the future.

So much for matters in connection with the professional practice side of architecture. Now let me glance at one or two subjects that may become

Important Factors in the Architecture of the Next Century.

First of all comes the question of the art of architecture as distinguished from mere building. I have already mentioned the debate as to whether in a competition the assessor should regard more the plan or the artistic qualities of the elevation and design. It has been suggested by an eminent Royal Academician that theory should be subservient to practice, and that the elevation is the growth from the plan—the plan first, the elevation after—a principle, he considers, too often neglected. I cannot think that any hard-and-fast principle can be laid down. Architecture is neither planning nor making fine elevations but a combination of the two—and of much more besides. For there is a subtle and not easily defined quality to be found in all good architecture, one not always included in convenience of plan or propriety of design, which the world has agreed to call "Art." Tolstoy says: "Art is a human activity transmitting feelings," and the stronger the "infection" the better the art.

It is our misfortune just now to have urged upon us comparatively trivial and local views of this great subject. We have had this century a Classic revival, which would take a temple portico as a model and plant it on to a domestic palace as fitting rural architecture. However charming this may appear in a distant view of a large landscape, as at Prior Park, at Bath, nothing could be more incongruous with domestic English life or with the severity of the weather in this uncertain climate. This class of work did not "infect" more than a portion of the community predisposed in its favour.

We have had enthusiasm for mediæval art reproducing for modern requirements and worship fourteenth-century churches, complete in all their parts—or introducing ecclesiastical details and construction into modern domestic work, regardless of the difference in times, politics, social life or thoughts, and of the eternal fitness of things. This class of work did not "infect" more than a portion of the community who were educated to appreciate the influence.

It is a matter for serious regret that the East, and especially India, the cradle land of much that we most prize in Europe, is so entirely neglected by our students and professors. Indian architecture has a whole world of instructive examples of grandeur of proportion, picturesque grouping, perfect planning, and beautiful detail, besides an indescribable nameless poetry nowhere else to be found.

I do not suggest that we should copy Oriental architecture, any more than that we should copy Greek or Egyptian work, but that it should be seen and studied as an educational process, as well as for its own sake, and the more especially as Great Britain is now not only a European but an Asiatic power.

As to the next century: among its many problems it seems likely that some revision of our present methods of

Church Planning

may result from the needs of great congregations in our cities and large towns. It is not dissent alone that now commands large crowds and requires expanded tabernacles. The Mother Church also needs grand areas for worship where all can see and hear.

Perhaps in the near future it may be thought advisable to consider the plans of such buildings as the ancient Basilicas, the early Church of Santa Sophia at Constantinople, the Pantheon at Rome, the grand Oriental mosques, and the Church of Santa Maria del Fiore at Florence, with a view to avoid the blocking of the central portions of our large churches or cathedrals, after the mediæval manner so detrimental to congregational worship. We may then possibly find a way to bring the altars forward instead of placing them some hundreds of feet away from the nearest part of the congregation. I can conceive that such a building might be a glory to the century, not necessarily of cold, Classic details, or of Oriental feeling, or of severe Gothic, but nervous with the life and aspirations of modern times and beautiful in proportion and detail and in sculptured lessons.

Also as to our streets. London is being fast rebuilt—certainly in the central part. I would ask on what principle is this rebuilding being done? Is more forethought being expended than in former centuries? Is new London to be allowed to grow up with as little apparent design as a vegetable — controlled by a thousand influences, some hidden, some vainly directed?

A New London.

One cannot but feel that a step in advance has been made by the fact of the London County Council becoming alive to the importance of obtaining thought out schemes and designs for future improvements, though only in part before rebuilding is commenced.

The Strand to Holborn scheme is clearly a movement in the right direction, recognising as it does a general principle, however ill-advised the County Council may have been in the particular method of applying it; for we cannot but regard as unfair their conditions to the architects, and unsatisfactory the nature of an arrangement by which, even when designs may be settled on, there is no guarantee or certainty that they will be carried out.

But if in the rebuilding of London our authorities are wise, at an early date in the new century plans should be prepared showing future lines of building and increased width of thoroughfares; and all future building operations, private or public, should be controlled within these lines, no matter at what cost.

It is worth considering whether shops should have arcades over the footpaths, for the protection of pedestrians from rain, snow, and sun. There are objections on the ground of police supervision and light, but they are by no means insuperable, while undoubtedly the arcade gives the architect his only chance of making a shop front constructively reasonable.

London is unique in the fact that, notwithstanding its wonderful and continuous growth through many centuries, its centre, the City, has always been fixed. In any future reconstruction this centre must be the starting-point; the main arteries for traffic must be arranged to radiate from this centre to the surrounding suburbs.

The Arts and Architecture.

But this is not all. We have heard at our Congress last session of the necessity for collaboration between the architect and sculptor and painter; that is to say, closer union of all the arts is needed in the master art of architecture. Painting *may* have more scope in the architecture of the future, in the way of internal decoration, than during the past century, and there are many signs of this coming to pass.

But sculpture *must* have much to do with the design of the external architecture and rearrangement of new London if it is to be worthy of this great empire. Nothing can be more wasteful and absurd than to finish sculpture placed at a great height above the eye to the extent that the figures on the top of Milan Cathedral are finished. Or, again, I cannot think it happy to place sprawling, meaningless figures on the sides of window pediments, like some I noticed the other day—out of scale, coarse, and so large in comparison with the pediments that they looked scarcely capable of sustaining their weight; or, on the other hand, to place in similar positions rows of nude children, repeated *ad nauseum*, is a costly, meaningless, and futile decoration. Nor can I think yards of repeated terra-cotta ornamentation excellent. But much depends on the manner of the introduction of such embellishments. Sculpture in connection with architecture should not be the first object to attract the eye, but should take its place as part of the general scheme, adding to and not upsetting the general harmony, helping the architecture to tell its tale.

The sculptors of the middle ages, no mean artists, seldom attempted the "insulated" statue. At a later date Donatello produced statues independent in themselves, and not "mere adjuncts" of architecture.

The critics who uphold this doctrine of insulation, as we may call it, doubtless think of the matchless single figures of Greek workmanship, of which copies and a few originals are seen usually in a fragmentary state. But they probably forget that the majority of these works, including even the magnificent Venus of Milo, now standing in solitary grandeur in the Louvre, were originally part of an architectural composition. I cannot help feeling that sculpture divorced from architecture loses greatly in value, character, style and teaching.

There is a great gulf between the portrait statues and busts of Rome, conceived and executed in a style which was then a vital force, set in congenial architectural surroundings, and our forlorn and sparsely sprinkled public effigies.

A building is of itself an historical monument, upon which, more fitly than by any insulated work, the varied aims, achievements, interests, and story of the time can be permanently inscribed. I do not mean to say we should have no independent statues at all, but rather that when we do have them, even in our public places and gardens and on our bridges, they should form part of a properly considered architectonic scheme.

But there must be in our future progress not only collaboration with the arts in sculpture and painting, but also with science in engineering. If architecture neglects scientific construction in other materials than brick and stone, it is not properly fulfilling its mission On the other hand iron and steel could certainly be used without the meagreness or aridity of effect to which we are unhappily so much accustomed. It certainly is not impossible to make a beautiful iron bridge or roof.

I have now, gentlemen of the Institute, ventured to direct your attention to a few of the subjects that appear to me to call for our consideration, and in some cases for our united action, if there is to be material progress in our art during the next century.

But one cannot expect that a large body will in all these matters see eye to eye with one who, though occupying this chair, is but an individual. I have, however, at least expressed some of my most earnest personal convictions, and as such I commend them to your consideration.

A vote of thanks to the President was proposed by Mr. Alfred Waterhouse and seconded by Mr. Bodley, the latter referring to the proposal to alter the steps of St. Martin's Church, which he strongly deprecated. Mr. E. R. Robson and F. C. Penrose agreed that the scheme was a most ill-judged one, and they sincerely hoped that it would not be carried out. The meeting then terminated.

The Shrine of Shakespeare.—On the moment of going to press we learn that Sir Theodore Martin has decided not to proceed with his proposal to erect an alto-relievo of his late wife in the chancel of Holy Trinity Church, Stratford-on-Avon (see page 266).

A COUNTRY HOUSE ELECTRIC-LIGHT INSTALLATION.

By K. S. MACKINLAY.

(*Concluded from page* 238, No. CCXCVIII.)

IT would be useless to go into the comparative advantages and disadvantages of wood casing, steel conduit and other methods of wiring here, as making such a comparison would necessitate the consideration of large buildings such as town halls, factories, &c., which would be outside the subject of this article. Apart, however, from making the comparison from an electrical point of view, in private houses wood casing is preferable to barrel or conduit for one or two reasons. For instance, it is desirable that the circuit mains should be easily accessible, so that alterations can be made or extra lights added at any time. For this purpose wood casing can be used on the surface of a wall, where barrel is, of course, out of the question, and chasing the latter into walls necessitates redecoration; again, casing can sometimes be advantageously used to feed wall plugs, treated perhaps as a skirting or dado rail. Where the house is to be redecorated throughout in any case, a system of metal insulation is undoubtedly the better and safer method to employ, though rather more expense is incurred.

There is a system of wiring known as the "concentric" system, in which both the conductors are made up in a special manner to form a single cable, but as this entails the use of special fittings, switches, &c., it does not lend itself very well to use in private houses.

The Institution of Electrical Engineers have been trying to bring about the universal recognition of one set of wiring rules, which should be made as comprehensive as possible, to suit all the several conditions of different installations. The Institution already have a set of rules, which are probably the best that have been drawn up, and if architects would always specify the "Institution Rules" for the wiring of their buildings it would help to promote a much-to-be-desired object. An important thing in the wiring of a house is the

Planning of the Circuits.

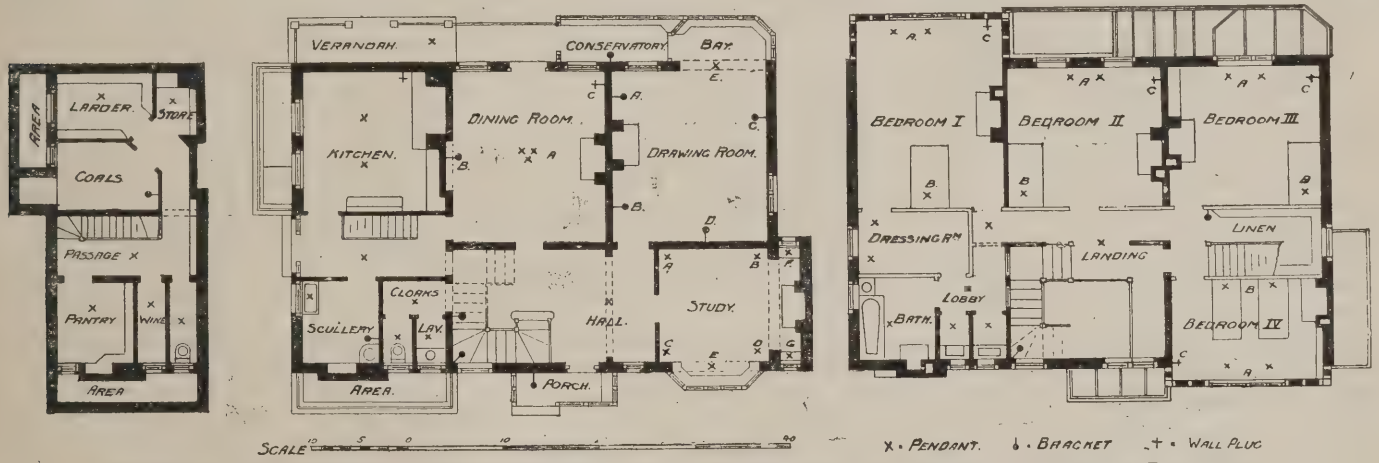
It is most general to put all the lights which are nearest to each other, or which come in the most direct run of the wiring, on one circuit (of course, until the number of lights desired on each circuit has been reached). This is done with the object of economising the materials and labour; but at a slightly greater cost more satisfaction can be obtained in the way of convenience, or rather preventing inconvenience, by introducing two distinct circuits into every room; if this is done, in the event of a circuit-fuse melting, no one room can be put into complete darkness. In private houses where balls, dinners, &c., are at all frequent it is clear that an arrangement of the circuits in this way is most advantageous, and worth a little extra expense.

The plans of the house for which the electrical arrangements given in the previous article were designed are shown here, with the positions of the lights indicated in each room. The list of circuits, which are planned on the lines mentioned above, is given at the end of this article.

The mains from the engine-house are brought into the house in the basement, where a main switch, main cut-outs, and the distributing boards are fixed. It is desirable to have a meter somewhere in circuit, so that a check may be kept on the current consumed. This may be fixed in the engine-house or in the house itself; perhaps the former is the better place, as there the current used by the lights in the engine-house can be registered as well as the rest. At the fuse-boards the current is split up into ten circuits, nine of 5 ampères and one of 2½. The main casing runs up through the wine cellar and the ground- and first-floor lavatories.

The arrangement of the switches for the various lights should always be considered in detail before an installation is commenced at all, for one switch well or badly placed means that the convenience or inconvenience of the position is realised not once, but time after time, most likely for years. Many persons about to install will leave the positions of the lights and switches entirely to the contractor, who, in nine cases out of ten, will simply put in as many as he thinks his client will agree to in certain positions which have by repetition become "usual," but are not the most reasonable or by any means the best; and when they move into the house they find that the positions do not in the least fit in with the arrangement of the furniture, and the whole thing is most unsatisfactory. Others go over the house with the contractor and decide upon the positions of the various fittings, &c., without previously having given the subject the least consideration: they will ask what the contractor advises, whenever they are in the slightest doubt about anything, and in consequence they get very nearly the same result as those who leave the whole thing to the contractor. For example, instead of seeing other installations, trying switches fixed at different heights and in different places, and deciding for themselves on the most convenient positions, people will wait until the time comes and then ask the contractor what the best height is; he, in his turn, instead of mentioning a height and stating what he considers is the best, will probably say: "Some people prefer one height and some another, we *generally* put them such and such a height," which does not answer the question at all; however, a decision will most likely be made in favour of the height named, which will prove perhaps satisfactory, perhaps unsatisfactory.

Switches are fixed by most contractors at a height of about 4ft. 9in. or 4ft. 10in. from the floor, presumably for some reason, if no special height is specified. How this custom originated it is difficult to imagine, as it is most inconvenient to turn a switch on and off when fixed at this height, and, say, inside a door; and certainly the ordinary type of switch, either tumbler or otherwise, can claim no artistic merit. There are, of course, switches with covers of hammered copper, silver, and so on, which are most ornamental, and others again with professedly "ornamental" covers, which are simply tawdry. The best and most convenient height for a switch is undoubtedly on a level with the door handle; it may often be fixed outside the room with advantage, in which position it can be switched on and off without attracting attention. In bedrooms one might, perhaps, be liable to leave lights burning if the switches were outside, but this is quite a matter of preference.



Lights on staircases and in passages can be controlled from two distinct points by the use of what are known as "two-way" switches. The judicious employment of these entirely does away with the necessity of leaving lights always burning on landing, &c., which tends more than ever to make the cost of electric lighting compare favourably with that of lighting by gas. In any room having two separate doors the lights, or, at all events, some of the lights, should be arranged to switch on and off at either door. A much-discussed question is that of the best scheme for

Lighting the Dining-room.

The most usual is a three-light counterweight pendant hanging about two or three feet above the table; this fitting has a shade or else a silk flounce to shade the diners from the light. This style of fitting may have its advantages, and, if a good colour is chosen for the shade or flounce, it certainly shows off the glass and silver to great advantage, but, on the other hand, a good design is so rarely met with, and the shades are, as a rule, so very ugly; further, unless there are other lights burning, the rest of the room is very dark and, in contrast to the brilliantly-lighted table, looks cold and cheerless.

Another method is to employ imitation candles or standard lamps. The most artistic effect can probably be obtained in this way, but there is the disadvantage either of making holes in the table-cloth or the table, or else of a flexible wire. Another scheme is that of using the reflected light given from hidden lamps; this effect is the nearest approach to daylight of any method of utilising incandescent electric lamps, but it is also the most expensive, as much more current must be consumed to give enough light, which, when reflected, is sufficiently intense.

The last way is to use no special lights for the table, but simply to light the room as a room, with brackets, or pendants, or a centre fitting (other than the counterweight pendant with a shade). There is nothing to be said against treating a dining-room in this way so long as good fittings are chosen. Brackets designed as old lamps are sometimes very artistic, and there is no reason why a dining-room should not be lighted entirely by these. In my plan I have indicated a three-light fitting in the dining-room, which is intended to be one of the type in which the lights are quite close up to the ceiling, with reflectors behind them designed as leaves; these fittings are made in copper, iron, and brass and are finished in a variety of ways, the whole effect generally being most decorative and artistic, and not very expensive. The light coming from so high a point is very diffused and casts hardly any shadow, and the reflection from the polished metal increases the light by about 20 per cent. What are known as "electroliers"

BASEMENT, GROUND-FLOOR AND FIRST-FLOOR PLANS OF HOUSE, SHOWING DISPOSITION OF LIGHTS AND FITTINGS.

are generally unsatisfactory in that, like the majority of brackets, although some are well designed, they are anything but decorative, and the lights, which are rarely shaded, are too much on a level with the eye.

Wherever fittings are designed on the same lines as gas-fittings, i.e., with a tube running from the base to the end, it is impossible to avoid a look of rigidity and ungainliness except in very large fittings. There is, however, nothing inartistic in silk-covered wire, and the idea of introducing a tube, which is so detrimental to the appearance of a fitting, to hide this is to me quite inexplicable; and yet this is so often done. It is surprising how few firms there are who have really good fittings, and how some of those who sell but do not manufacture them, who, therefore, have the pick of the manufacturing houses, have such comparatively poor show-rooms. To pass on to

The Drawing-room.

It is usual to light this room by brackets, as ladies prefer a side light to a top light; but if the lights are not shaded they should be kept as high as possible, as a bare light anywhere near the level of the eye is unpleasant and injurious to the eyesight. One frequently hears people say that they will not have electric light installed because it "is so bad for the eyes"; if anyone's eyes are affected, it is either for the above reason, or else the trouble is caused by using too much candle-power, or having clear lamps exposed to the eye. It seems a pity that electric lighting in general should be blamed for an ill caused by its erroneous application.

In connection with the erroneous application of the electric light, picture lighting suggests itself. In the discussion following a paper read by a prominent electrical engineer before the Royal Institute of British Architects, a member of the Institute was giving his opinion against the lighting-up of pictures with special lights, but in replying the reader of the paper said "that this really was not the verdict of well-known artists." At all events, the design of some of the reflectors at present on the market would not tend to induce a further adoption of picture lighting; but as regards the principle itself some pictures can be lit up by an artificial light to great advantage; to produce an artistic effect, however, a certain knowledge, not only of electric lighting, but of painting is necessary. For instance, to light a number of pictures by putting a reflector or two under each, treating all in the same way, would completely ruin whatever artistic value the picture itself might possess under normal conditions, unless by a mere coincidence the pictures all required the same treatment.

The library requires plenty of light so that books can be easily seen and identified when they are in the bookcase. I have indicated four pendants or ceiling lights on the plan; fittings, with cut-glass, cone-shaped globes, close up to the ceiling, are a good type for single lights. It may be argued that putting these lights so close to the walls means a loss of light, but it must be remembered that book-cases are most likely placed, if not fitted, round the room, and thus there is plenty of light on the books. The

Indiscriminate Use of Wall-Plugs

should be guarded against, and where they are used the positions should be chosen with care, on account of the flexible wire stretching about and causing accidents; and in the event of a writing-table being placed in a bay window, or in any similar case, a pendant over the table, not too high up, should be preferred to a table lamp. If the selection of the positions of the lights be left to the contractor, he will almost invariably put a wall-plug on either side of the fireplace in every reception room, or, if he only puts one, he will put it on whichever side he fancies at the time.

It is well to put one wall-plug in every reception room and bedroom, with the idea that a standard will be required for a writing-table in each room; the position is determined by the position of the window; it is quite safe to take the writing-table as being placed in such a position that in the daytime the light comes from the left; the wall-plug must therefore be placed in such a way that when the standard is on the left-hand side of the table the distance to the wall-plug is as short as possible.

Standards are used a great deal at the bedside—to me another curious idea. The position, when trying to read in bed with a standard by the side of the bed, cannot possibly be comfortable (and again, there is the flexible wire), and if there are any bed curtains a bracket is impracticable; surely, then, the most suitable fitting for the bed is a counterweight pendant fixed, of course, as far back as possible. It is strange these fittings are not more used in this way, seeing that they can be fixed to bring the light in the best possible position for reading, can be pushed up out of the way in the day-time, and do not interfere with bed curtains, unless there is a canopy over the top, and even then are more possible than almost any other fitting. I say "almost" because there is on the market a special standard which is made to clutch on to the bedstead itself, which is a very serviceable fitting. For the dressing-table two counterweight pendants are perhaps the best thing; imitation candles may be preferred in some cases, and a standard on either side is possible. I have not marked the positions of the switches on the plans, but they may be taken to be in conformance with the observations I have made on that subject.

Messrs. E. H. Shorland and Brother, of Manchester, have recently supplied some of their patent Manchester grates to the New Infectious Hospital at Gloucester.

New Scientific Laboratories at King's College have been erected. The whole of the South wing of the college has been raised by an additional storey, which includes the new geological, comparative anatomy, and botanical departments, while the second storey of the north wing, comprising the physiological and bacteriological departments, has been largely reconstructed, as has also the fine room on the first floor now allotted to the architectural department. In all the new rooms electric light, gas and water are laid on, and special care has been taken to obtain in every case a natural light as good as possible. The cost of the extension has been nearly £20,000.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Theatre of Marcellus, Rome.

GRANGE-OVER-SANDS. — STUDENT writes: "In Phené Spiers' 'Orders' the Doric from the theatre of Marcellus, Rome, is given, but incompletely for my purpose—to make a drawing of it similar to sketch (not reproduced). Could you please give me the height from the base of the column to the top of the impost and a brief description of this theatre? I have Taylor and Trevy's 'Rome,' but find no mention of this building. In what book or books can further particulars be found?"

The height from base of columns to top of impost is 17ft. Neither the columns nor the imposts have moulded bases, and there is no archivolt; this refers to the lower Tuscan arcade. The second storey is Ionic, and there was an attic, with Corinthian columns and rectangular windows. It is all worked in travertin, once covered with the hard white stucco of pounded marble. The details are much more delicate and refined than those of the similar arcades in the Colosseum. Little of the Scena now remains above the ground, but much of the arcading of the curved exterior is still standing, though half buried in the ground. Plans, elevations, and sections will be found in Canina's great work, *Edifizj di Roma Antica*. Begun by Julius Cæsar, the theatre was finished by Augustus, and dedicated 13 B.C. under the name of his son-in-law, Marcellus. In the Middle Ages it was made into a fortified palace, and here Pope Urban II. found shelter and died. The ruins now support the Orsini Palace. J. M.

Cubing Buildings.

LONDON, S.E.—F. P. writes: "Referring to the cubing of a building for the purpose of roughly estimating its cost, it does not seem difficult to calculate the cube contents of, say, a house; but I am told just enough to gather that there are different modes of allowing a capacity to foundations, and perhaps roofs, &c. Kindly give me some information on this subject."

Leaning's "Quantities," which is the standard work, says: "The most usual practice is to multiply the outside length of the building by the breadth, and the result by the height from the bottom of the footings to half-way up the roof. These measurements, to be of any value, must always be done in the same manner, and must comprise the whole contents, including the walls. Disregard chimney-stacks, buttresses, and dormers, unless in unusual number. A different price per foot may sometimes be adopted for the various parts, but not often. It is more convenient to adopt one uniform rate. For boundary walls and such works an approximate estimate should be made and added to the price arrived at by cubing." There are other methods, but this is the best. The rate for a private residence averages 7d. per cubic foot. HENRY ADAMS.

Design for Bridge.

CLITHEROE.—BOWLING writes: "We send a plan and section of a bridge over a brook crossing the highway. The top of the bridge is to be built of steel girders and concrete. The girders are 10in. by 6in., 44lbs. per foot, and the safe distributed load for span is 16·4 tons per girder. The concrete is 15in. thick, composed of three parts of stone broken to pass a 2in. gauge, two parts of clear washed river sand, and one part of best Portland cement. Would you please state the safe moving load, and the dead load, which this bridge will carry. Do you think it necessary to put iron curved plates between the girders to lay on the bottom flange, and if so will it weaken the girders to bolt them to the bottom flange, say, 2ft. apart?

Can you give a formula for finding the bearing strain of concrete?"

The safe load on a 10 by 6 by 45lb. rolled steel girder 18ft. span is 12.8 tons. With an average thickness of concrete 15in. and roadway material 15in., and girders at 3ft. centres, the dead load on each will be 7·2 tons, leaving 5·6 tons for live load, or 2cwt. per foot super. With this limit it will be necessary to put up a notice forbidding loads to pass over which are greater than five tons, or one ton per wheel. Iron curved plates will not be necessary below the concrete. It would certainly weaken the girders considerably to bolt such plates to the bottom flange. The following formula gives the supporting power of concrete in flat slabs of uniform thickness laid between walls or girders:—w = cwts. safe load per ft. sup. at end of three months; t = thickness in inches; L = span in feet—$w = 4\frac{t^2}{L^2}$. Half this load may be carried at the end of one month, but the centres must not be struck, at the earliest, till a fortnight after laying.

HENRY ADAMS.

Advantages for Study in London and the Provinces.

OSWESTRY.—O. R. writes: "Kindly inform me whether there are any special advantages for study to be gained by being in London in preference to any of the other large cities?"

Three are no special advantages to be obtained in London beyond, of course, the use of the British Museum and the Architectural Association. The Royal Institute of British Architects has a very fine collection of architectural books for the use of its members and students, but most of these works would probably be found upon the shelves of the provincial sccieties or technical institutions. In most large cities, courses of lectures and classes in building construction, &c., are available, and a student in Manchester, Birmingham, or any other large town would have as good facilities for study at his command as his London brother.

R. W. C.

Builders' Book-keeping.

HULL.—B. B. writes: "Could you give me any information about a good system of builders' book-keeping?"

We have several times stated in reply to queries that Saker's "Builder's Book-keeping: a Perfected System" is the book we recommend. It is published at 95-97 Finsbury Pavement, E.C., price 3s. 6d.

Gauging Portland Cement.

LONDON, N.—J. L. writes: "I am desirous of doing some cement dressing. Will you kindly inform me what I should mix with the Portland cement to make it bind well. I have tried mixing with water only, but the cement rubs off in a powder as soon as it is dry."

Obviously the cement used was of inferior quality or improperly gauged. Water is the natural liquid for gauging Portland cement, but it should be clean and free from foreign matter. For casting cement dressings the cement should be mixed with an aggregate, in the proportion of three to five of the latter to one of the former. The aggregate may consist of broken stone, brick, granite, slag, gravel, or coke-breeze. The size of the aggregate is regulated (to some extent) by the size and purpose of the cast, and may range from ¼in. to 2in. The aggregate should also be angular, and of mixed sizes, so as to bond better together. The addition of a small percentage of sand tends to form a closely-gra ned surface.

W. MILLAR.

Ancient Lights.

BANGOR, N. WALES.—BANGOR writes: "Can I erect a back wing as shown on the enclosed sketch (not reproduced) without injuring my neighbour's ancient light? My intention is to erect a new wing abutting against the fence wall, keeping the eave considerably lower, thereby allowing the light to fall at an angle of 45deg. to my neighbour's window."

Draw a straight line from the sill of your neighbour's window to touch the highest point of the existing obstruction to his light, which in this case is the eaves of the existing building. Anything extending above this line would be an obstruction to your neighbour's light, and it appears that part of the proposed building would so extend. The obstruction would not, perhaps be a very serious one, and you might come to some arrangement with your neighbour, e.g., to face the new wall with white glazed bricks; otherwise he might procure an injunction to restrain you from building so as to obstruct his light. There is no special virtue in the angle of 45deg.; the question of obstruction is a question of fact in each case.

G. H. B.

How to Use the Centrolinead.

NORTHAMPTON.—STUDENT writes: "I should be glad to know how to use the ordinary centrolinead. Is an imperial-size drawing-board large enough for a perspective view of a building 120ft. long and 45ft. high, drawn to ¼in. scale; i.e., can the centrolinead be fixed on the board for that purpose, or is a larger board required?"

The centrolinead used in making perspective drawings merely furnishes the means of drawing various lines to the same vanishing point; it does not find the vanishing point or the other points from which the lines are to be drawn. A perspective drawing looks best when the object is contained within an angle of vision of 30 deg., or in other words the point of sight should be at a distance of not less than twice the greatest dimension of the building as seen from the direction selected. The whole height of perspective view should not be more than two-thirds the height of the picture. Therefore, on a sheet 30in. by 22in., with the longest dimension horizontal, the greatest height of building, allowing for border line, would be about 12in., which at ¼in. to the foot would take in 48ft.; so that it would appear that the proposed building could be drawn to this scale on an imperial sheet, as shown at Fig. 1. The following description of the use of the centrolinead by H. B. Bryan, Esq., is published in the instrument catalogue of Messrs. J. and W. E. Archbutt, 201 Westminster Bridge Road, London:—"The centrolinead, invented by Peter Nicholson, is a most useful instrument for perspective drawing, as by its means the vanishing point, often inaccessible on a drawing board, is easily determined. The centrolinead may be set to draw lines to a vanishing point, at any distance from the point of sight, by the following method:—The horizontal line (A B in Fig 2) being drawn, the point of sight marked as desired, near the edge of the board, on the same side as the distant vanishing point, draw S′ S″ perpendicular to A B. From the point of intersection, C, set off 8in. above and below to S′ S″. Fix the studs at these points, so that the *edge* of the stud coincides with point, which must then be between the stud and the point of sight. The distance from the point of sight to vanishing point being known, the distance from C to vanishing point is the difference. Then divide 64 by the distance from C to vanishing point. The result, which is C D, must be set off by a scale divided to tenths of an inch. Draw lines from S′ S″ to D. Lay the short arms of the centrolinead *exactly* along the lines D S′, D S″, and the long arm along the line A B. Screw up tightly. Example:—Let the distance from C to vanishing point be 123in. $\frac{64}{123} = 52$ = the distance from C to vanishing point. Draw lines from studs to D. Lay the short arms along these lines. Adjust long arm to horizontal line and clamp. The constant 64 is the square of 8, the distance of the studs from the horizontal line. Any distance, as 6, 7, 9 or 10, may be used if more convenient, when its square becomes the constant to be used."

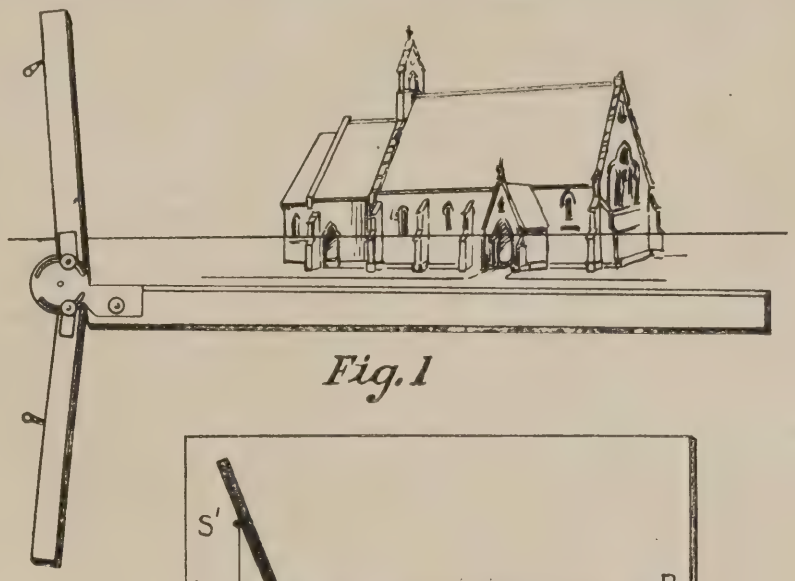

Fig. 1

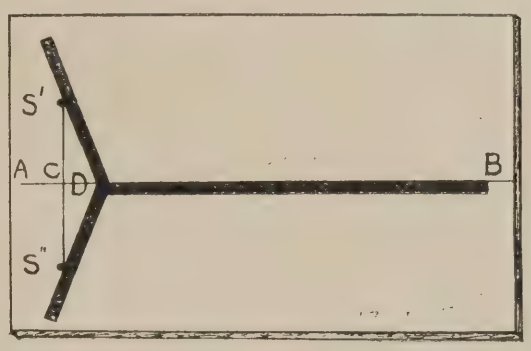

Fig. 2

METHOD OF USING THE CENTROLINEAD.

HENRY ADAMS.

Iron Roof Truss.

ST. LEONARD'S-ON-SEA.—E. D. B. writes: "I am studying a wrought-iron roof truss for 45ft. span given in Mr. Adams's "Practical Designing of Ironwork." Could you say how the connection of short strut and tie-rods is formed? Is the larger tie-rod welded to the smaller one, or have all the tie-rods separate eyes, the whole secured by a bolt? Also, how should the diameters of the bolts be calculated?"

The connection of short strut and tie-rods is shown in Fig. 177, Plate 14, of "The Practical Designing of Structural Ironwork" (Spon., 8s. 6d.). The two portions of the main tie-rod are welded together at the eye, upon one side of which the inner tie comes, and upon the other side the strut, the whole being connected by a bolt and nut passing through them.

When a tie is attached singly by a bolt at right angles, the diameter of bolt should not be less than that of the tie, but where two rods in the same line are welded together they put no stress on the bolt, and the latter is then made to suit the single tie. For this joint in question a $\frac{7}{8}$in. bolt is sufficient. The diameter of bolt may be calculated for the shear stress, according to its sectional area, allowing 4 tons per square inch single shear or 6 tons double shear. HENRY ADAMS.

Stability of Piers.

SOUTH SHIELDS.—A. B. C. writes: "I should be glad to have the opinion of one of your experts as to the stability of the arrangement shown on the accompanying drawing. Is the abutment sufficient to withstand the thrust of the arch?"

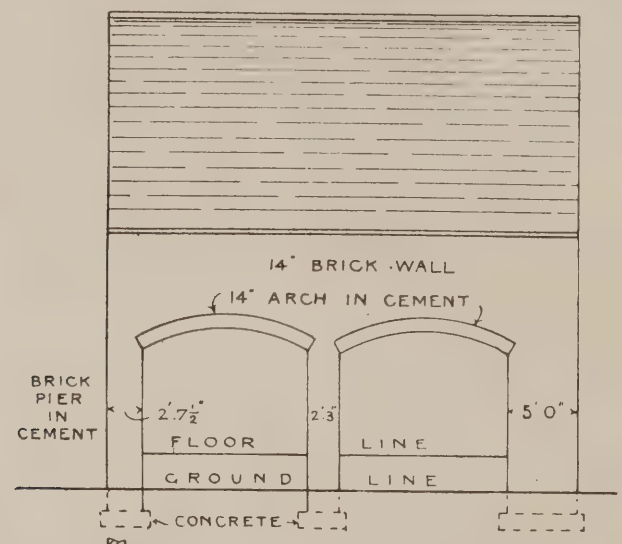

Fig. 1

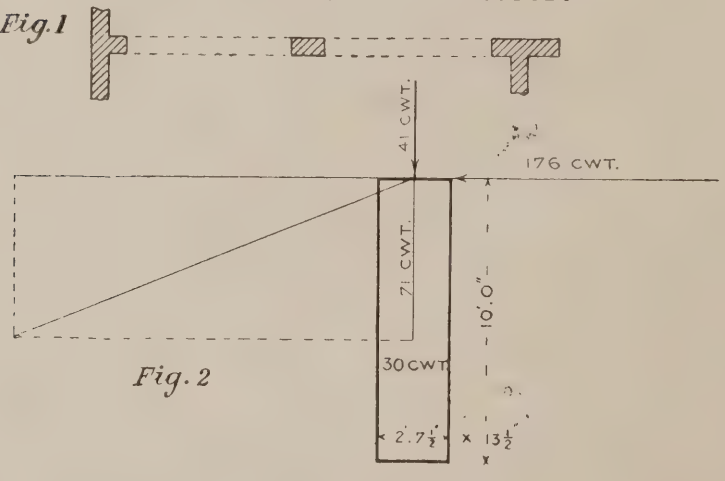

Fig. 2

STABILITY OF PIERS.

The load on the arch, Fig. 1, is not given nor the means to compute it, but assuming it to be about 16cwt. per foot run, and the arch 11ft. 6in. span with a rise of 1ft. 6in., the thrust will be $\frac{wl^2}{8r} = \frac{16 \times 11{\cdot}5^2}{8 \times 1{\cdot}5} = 176$cwt. Assuming that the thrust is to be taken by the brickwork at the pier only, then we have weight of pier, say 30cwt., and the diagram of thrust as shown in Fig. 2, showing that the thrust is certain to push over the pier upon the ordinary assumptions. Unless an outside buttress can be applied, the pier should be widened to the same as the other side, namely, 5ft., the openings reduced in width, the middle pier increased to 2ft. 7½in., and the rise of arches increased to 2ft. The above information will enable calculation to be made for any altered dimensions that may be decided upon. HENRY ADAMS.

Thrust of Arch and Moment of Inertia.

BURTON-ON-TRENT.—(1) "Why should the moments shown in the enclosed sketch (not reproduced) be taken near the middle of the skewback instead of at the bottom corner of the soffit? (2) In finding the area of a wrought-iron section, so that the moment about the neutral axis equals effective area plus the total arm, how would you allow for bolt holes as shown on the sketch sent herewith (not reproduced)? (3) Where can I obtain a syllabus of the geometrical drawing required for the preliminary examination of the Institution of Civil Engineers?"

(1) When the line of thrust is fully worked out in a properly designed arch it is found usually to pass through the skewbacks at one-third of their length from the springing, and through the crown of arch at two-thirds the depth from soffit. In dealing with the moments on a semi-arch, as in sketch, these points are taken because the line of thrust represents the theoretical arch contained within the clothing of practical masonry. (2) The bolt holes in the flanges of a rolled joist or other section virtually reduce the width of flange and are allowed for accordingly in the calculation or graphic diagram. In the web they are of so little consequence that they are usually not considered; if they were it would be merely a question of $-bh^3$ as part of the general formula. (5) Application should be made to the secretary of the Institution at 25 Great George Street, S.W., for copy of regulations and last examination paper.

HENRY ADAMS.

New Council Offices and a New Church for Kilmalcolm.—The Parish Council of Kilmalcolm have decided to erect new Council offices. Plans have been prepared and the contractors fixed, and when the formal approval of the Local Government Board is obtained work will be proceeded with immediately. The cost is estimated at about £1,200. The members of the United Presbyterian Church have decided to erect a new church on a piece of vacant ground near by. The church will cost about £3,000.

Professional Practice.

Edinburgh.—The Diamond Jubilee new pavilion at the Edinburgh Royal Infirmary, which was recently opened by the Princess Henry of Battenberg, is to be specially devoted to the treatment of diseases peculiar to women. About half the cost of it will be defrayed from the Diamond Jubilee Fund raised by the citizens of Edinburgh in 1897. The building, furnishing, and equipment of the pavilion will cost about £40,000. The new pavilion stands on the ground immediately to the west of the medical pavilions purchased by the managers from the directors of the Sick Children's Hospital. Its length is 220ft. by 65ft. in width. Designed by Messrs. Sidney Mitchell and Wilson, architects, its style is a free treatment of the Scottish Baronial, dictated more or less by the character of the adjoining pavilions. It is, however, larger in size than these, and this fact and the special purpose which it is intended to serve have led to certain changes in its outward appearance as compared with the main buildings. The new pavilion is built of red Corsehill stone, the others alongside of it being in grey sandstone. It is five storeys high, consisting of basement, three floors of wards, and attics. At the south end the corner turrets are octagonal, being for baths and ward lavatories. They rise to a height of 95ft. Between them are open balconies opening from each ward. At the north-east angle of the pavilion there is a large square tower rising to a height of 100ft., in which has been constructed a spacious staircase, as, also, in the upper stages, electric fans for the ventilation of the building. On the basement floor a new bathing establishment is placed, containing a Turkish bath with three hot rooms graduated in temperature, a douche room, vapour, needle, sulphur, electric and other medicated baths. There is a cooling room, 70ft. long by 10ft. in width, and provision has been made for dressing-rooms, lavatories and accommodation for attendants. All this portion of the building is lined and floored with tiles of various patterns and colours. Between the bathing establishment and the ward above there is a strong double concrete floor with intermediate ventilated air space, so that the heat from the baths will not penetrate to the wards overhead. The new pavilion is connected with the main buildings of the infirmary by a covered corridor on the ground floor, and an open gallery on the first floor. The wards are in communication with each other by means of a staircase and a passenger lift, and separate lifts for food and coals. The staircase is completely cut off from the wards, at the different levels, by means of a ventilated corridor with glass doors. The ward on the ground floor above the basement is intended to be used as an ordinary spare medical ward. Its chief ward, 102ft. by 28ft., is capable of containing 22 beds with a window between each of them. On the northern end, which is divided into two halves by a corridor 10ft. wide, are a lecture room, three wards of two beds each for special cases, a convalescent room, 35ft. by 20ft., to be used also as a dining room, a nurses' room, ward kitchen, linen stores, and ward baths, lavatories, &c. The wards on the first and second floors are those specially designed for the treatment of the diseases of women. At the north end is a well-lighted corridor, on the right of which are the operating room, two special wards of two beds each, one of which will be used as an anæsthetic room, a demonstration or lecture room, a room for outdoor patients, and a physicians' room. On the left of the corridor are the ward kitchen, bath-room, lavatories, an isolation ward with one bed, nurses' bedroom and parlour, linen stores, &c. The main wards like that below them will be 102ft. by 28ft., and each contain 22 beds. The operating rooms have been tiled throughout, so as to make them as antiseptic as possible. The wards of the pavilion are not strapped and lathed; the plaster is laid on a brick lining separated from the outer wall by an air space. The floors are of iron and concrete, and the floor boards are nailed to a layer of asphalt laid on concrete; the building is thus practically fireproof. All corners throughout the building are rounded,

there are no cornices, and the mouldings on the doors and windows are of the simplest kind, in order to leave no place for the lodgment of dust. The attic floor contains 14 single rooms for nurses, and 7 rooms for servants, besides lavatory, bath, and box-room accommodation. The main lifts go to the attic floor. For illumination the electric light will be used. For heating, steam pipes and radiators will be employed. In each ward there will be an open fireplace to give a comfortable appearance. The contractor was Mr. Colin M'Andrew. At present there is being erected between this large pavilion and the laundry on the north two buildings of smaller size—one for the treatment of diseases of the ear and throat, and the other for diseases of the eye. The infirmary kitchen accommodation has also quite recently been overhauled and enlarged at a cost of about £6,000.

Fulham, S.W.—The foundation-stone of the new baths and washhouses in Melmoth Place was laid last week. The site, which was purchased in January of last year for the sum of £12,250 has an area of 51,978ft., the whole of which (with the exception of 40ft. on either side of the main front) will be covered by the buildings. The main entrances are situated in the central block in Melmoth Place, which has a frontage of 42ft., and separate entrances are provided for men and women. There are to be three swimming-baths, the men's first-class bath being 100ft. long and 30ft. wide; the second-class bath 140ft. by 33ft.; and the women's bath 60ft. by 20ft. Accommodation has been provided in the plans for eighty-four private baths, twenty-five of these being intended for the use of women, while in both the men's and women's departments first and second-class baths will be procurable. In view of the ever-increasing popularity of swimming entertainments, special arrangements will be made for large gatherings. Galleries running round both the men's baths will provide ample space for spectators, and two club-rooms attached to the first-class baths are designed to give cloak-room and dressing-room accommodation for competitors and performers. The public washhouse, to which entrance is obtained in Hartismere Road, contains stalls for sixty-six washers and a corresponding number of drying horses, and four hydro-extractors. The new buildings are being erected from the designs and under the superintendence of Mr. H. Dighton Pearson, A.R.I.B.A., of Chancery Lane.

Hunslet.—The new workhouse being erected for the Hunslet Union, off Wood Lane, Rothwell Haigh, is to be built on the pavilion system, and will, it is expected, be ready for occupation in December, 1902. Accommodation will be provided for 412 persons. An interesting feature, is the arrangement whereby the respectable married couples can spend their declining years together. For this purpose four cottages are in the first instance to be constructed. They will be entirely separate from the main building, and being close to the roadway, will have an independent entrance, so that the fortunate tenants need not, unless they choose, associate with the ordinary inmates of the institution. It was also proposed at one time to accommodate 28 imbeciles, epileptics and lunatics detained for short periods in special wards, but the Local Government Board, refused sanction to the scheme so far on the ground that imbeciles and epileptics should be provided for in separate institutions. The plans have accordingly been altered so as to include only short period lunatics awaiting the magistrate's order for detention in a regularly-constituted asylum, and these will be accommodated in a separate block capable of admitting three of each sex. In the infant buildings, which are to include the receiving wards, the tramp cells and the associated wards, 51 persons will be provided for. Fourteen cells will serve to accommodate the male tramps, and if more than this number apply for admission they will be placed in the associated wards, which are also to be the temporary home of the female tramps. Provision will be made in the main building for 94 males and 100 females, including the able-bodied, the aged, women with infants and the infirm not needing medica treatment. In the infirmary there is to be accommodation for 73 males and 78 females, and the plans also comprise an isolation hospital where cases will receive attention until such time as they can be removed to the general infectious hospital. The buildings will be lighted throughout by electricity generated by private plant. The estimated cost, inclusive of the site, is £65,000. Mr. J. H. Morton, of South Shields, who designed the new workhouses at Doncaster, Burton-on-Trent and Grantham, is the architect, and the contractor is Messrs. Harold Arnold and Son, Doncaster.

Leicester.—The Convalescent Home on the Charnwood Forest has just had a new convalescent home for children added. The site consists of two acres. The Home is a branch of the Charnwood Forest Convalescent Homes for the County of Leicester. The new Home is separated from the main building by a lobby, situated on the Brand Hill, at the upper corner of Hunger Hill Wood. Part of the grounds are left in their natural wild state, and shady walks and lawns, playgrounds, and kitchen garden made. The building is arranged for 26 children, and contains two large day-rooms, namely, a dining-room and a play-room for the children, sitting-rooms for the matron and nurses. Two staircases are provided in case of fire, and there are extensive kitchen offices, laundry, and stabling. The children's bedrooms are all on the first floor, and consist of four wards, having sleeping accommodation for 26 children. One ward is arranged as an isolation ward, with nurse's bedroom attached, so that in the event of any infectious illness breaking out, it can be completely isolated and provisioned from the kitchen separately. Cross ventilation is provided in all the wards, and the lavatories are shut off from the rest of the building on each floor by a passage with cross ventilation. The whole building is heated by hot water—both corridors, day and sleeping rooms—as well as by open fire-places, all rooms being also ventilated by means of inlet and outlet ventilators, so that fresh air is admitted and the vitiated air is automatically drawn off. The water supply is from the Leicester new reservoir, and the rainwater is collected in a large tank. The building is lighted by means of acetylene gas, made on the premises. Mr. Alfred W. N. Burder, in conjunction with Messrs. Barrowcliff and Allcock, of Loughborough, have been joint architects of the building, and the contract has been carried out by Messrs. Moss and Sons, builders, of Loughborough.

West Hartlepool.—The foundation stones of a new Congregational church and Sunday-schools being erected on a site at the corner of York and Park Roads were laid recently. The plans for the building, which have been prepared by Mr. W. Lister Newcombe, F.R.I.B.A., of Newcastle-on-Tyne, provide for a church with accommodation for about 800, on a site containing about 2,000 square yards. The main entrances will be from Park Road, and on the right of the main vestibule will be a cloak-room for ladies, and on the left a similar room for gentlemen, both having lavatory accomodation. The nave and transepts are to have side aisles, divided from the nave by arcading, and an uninterrupted view of the pulpit from every seat in the church will be ensured. There will also be a small gallery over the entrance vestibules and a large choir recess, with a space behind for the organ. On the left side of the choir recess will be the ministers' vestry, and on the right the choir and deacons' vestry, as well as a choir vestry with doors opening into the recess. The west portion of the site is to be occupied by a large assembly hall, 61ft. by 37ft. in dimensions, the entrance to which will be through a spacious porch, and opening off this hall will be three class-rooms, whilst at the rear of the hall four large rooms are to be provided for library, recreation and ladies' sewing rooms, all apartments having independent access. A commanding tower will occupy the north-east corner of the buildings, and the style of architecture to be adopted throughout will be Perpendicular Gothic. The total cost of the buildings, exclusive of the site, is estimated at £14,500.

New Patents.

These patents are open to opposition until December 10th.

1899. — Electric Lamps and Reflectors. — 20,877. THE IMPROVED ELECTRIC GLOW LAMP COMPANY, LTD., and A. BARNES; all of 103 Queen Victoria Street, London, E.C. This invention relates to a composition or paint for covering glass surfaces (such as the bulbs of electric lamps) with an opaque reflecting surface without the use of heat. The composition consists of cryolite in fine powder, 4 parts; oxide of zinc (powder), 10 parts; opal glass (powder), 8 parts; and silicic acid or silica (powder), 6 parts.

Clay Sinks, Seggars, &c.—21,710. J. WOOTTON, Park House, Coalville, J. STALEY, Church Gresley, and J. PARKER, Overseal; all in the county of Leicester. The object of this invention is to enable block sinks, seggars and similar articles to be made by power, improving and cheapening their production. This is accomplished by combining with a pipe-making and socketing machine, or a clay-pressing machine, a die, an adjustable clay-distributing block, and a rising and falling table.

Shop Windows.—23,474. J. G. STATTER and the VAPOUR PREVENTER, LTD., 68 Victoria Street, London, S.W. To prevent the deposit of vapour or moisture on shop windows, a chamber is provided at the bottom of the pane in which is placed a steam-heating apparatus. The heated air thus rises and impinges on the glass and so prevents it becoming clouded.

Slop Closets.—23,612. L. H. LLOYD, 48 Park Road, Lenton, Notts. This waste-water closet dispenses with the usual tipper or tumbler. Attached to the side of the pedestal is a chamber into which the waste water runs from the sink or bath. This chamber has two outlets, one an overflow (which goes into the pedestal), and the other controlled by a hand-rod.

Wall Tiles. — 24,615. B. J. B. MILLS, 23 Southampton Buildings, London, W.C. (communicated by F. Pagnon, Lyons, France). The tiles are first laid down on a flat surface and are then covered with the cementing material, in which a wire network is embedded. By this means the whole can be lifted and applied in one operation.

1900. — Tar Paving. — 13,168. J. WARD, Grange-over-Sands, Lancs. The body of the paving consists of relatively large tarred stones, to which small tarred stones are added, so that when rolled the latter fill up the interstices between the former and form a compact and durable paving.

The following specifications were published on Saturday last, and are open to opposition until December 17th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—20,378, HARPIN, burners for incandescent gas fires. 20,606, BARRY, means for raising, lowering, and discharging materials. 20,695, BACKHAUS, process for producing imitation paintings on glass and glass mosaic work as transfer pictures. 20,927, HADDAN (*Whiting*), sluice-gates for waterways. 21,985, PRICE, form of winding drums for winches and cranes. 23,026, WORTHINGTON, taps or cocks. 23,670, ROBINS, fixing of valves to pumps. 24,516, HORTON, decoration of walls, screens, and similar surfaces. 24,552, MAYNARD & WATTS, machinery for making bricks. 24,670, SQUIRE & SQUIRE, locks and latches. 25,679, LUCKING (*Pabst*), brushes.

1900.—622, BONHIVERS, incandescent arc and other lamps. 2,112, THOM AND MCCALL, windows. 5,288, GRANT AND MACPHERSON, covers for closet seats. 6,470, CAPRON, filters. 6,540, STEIN AND FREUND, electric railways on the conduit system. 8,751, PRINZ, curtain and other rods. 9,773, DAY, door holder. 10,778, SCHREYER, manufacture of objects in artificial stone. 11,453, COPE, heating apparatus for drying floors, kilns, or ovens. 11,517, ARCHER, manufacture of self-igniting gas mediums·

11,615, HIMMEL, appliances for gas in lamps exposed positions. 12,333, HUMPHREYS AND GLASGOW (*Gibbs*), gas burners. 12,390, GRAY, gas burners. 12,786, BORCHARDT, means for lighting gas. 12,861, LAKE (*Jewel Export Filter Co.*), purification of water and other liquid. 12 914, GREENWOOD, gas and vapour burners. 13 340. WIEGAND, gas cocks. 13,368, OUSEY (*Globe-Wernicke Co.*), doors for book and other cases. 13,684, PÉRILLAT, hydrocarbon burners for heating and lighting. 14,818, WESTAWAY, apparatus for compressing peat, leather, wood, or other material into blocks. 14,828, SCHNEIDER AND DERTZ, smoke-consuming furnaces. 15,418, GEIST, method of purifying and burning smoke by means of water under pressure, or steam. 15,964, STUMPF, window sashes and frames.

Law Cases.

Damages for an Unfulfilled Contract.—At the Blackpool County Court recently, before his Honour, Judge Coventry, Messrs. Crawshaw and England, builders, of St. Annes, claimed £245 2s. 6d. from T. A. Pollard, a Blackpool mason. Plaintiffs' counsel explained that on April 1st last year the defendant entered into a contract with his clients to do all the stone work in connection with some buildings at St. Annes, for the sum of £1,216 17s. In the agreement it was stated that the work had to be completed in 28 weeks, under a penalty of £6 for each and every week over that period. The contract was signed by defendant, and he deposited a quantity of stone on the works, but afterwards refused to go on. Counsel anticipated that part of the defence would be that plaintiffs, or one of them, agreed to give the defendant a guarantee of payment before he signed the contract. This, however, they absolutely denied, and the only contract made was the one before His Honour as to the stone work.—Albert Winstanley, architect, a member of the firm of England, Winstanley and England, of St. Annes, stated that he prepared the conditions of the contract for the stone work, and was present when defendant signed the contract. Pollard's first tender was for £1,069, but he afterwards told the architect that he had missed out an item in the last page of the quantities, and he would like to amend his tender. He was allowed to do this, and they ultimately agreed upon £1,216 17s. Defendant sent some stone down, and also some stone steps, which were not up to the standard, and were condemned by him (Winstanley). About May 24th, defendant asked for a guarantee, and after that he did nothing more. The next thing the architect heard was that defendant was not going to carry out his contract. The contract was afterwards let to a Mr. Shaw for £1,416 19s. 1½d. He carried out about half of it, and then went bankrupt, and the plaintiffs had to finish the job themselves. The defendant in his evidence said that England told him the owners of the land were going to finance the job, and if he got the contract for the masonry they would give him a guarantee. He pointed out to them that the granite and the stone carving would be expensive, but they replied that they did not want either. Yorkshire stone would be good enough. Before the contract was signed, an order was given for some steps for the café, which was part of the job, and they were sent the same day. He had not supplied any stones for the job under the contract, and none were rejected that he was aware of.—His Honour found a verdict for the plaintiffs, assessing the damages at £150.

The Submittal of Plans for Approval.—In the Queen's Bench Division on October 26th, before Mr. Justice Lawrance and Mr. Justice Kennedy, sitting as a Divisional Court, the case of the *Queen* v. *Nicholson* and another, Justices of South Shields, and Wilson, ex parte Hayton, came on for argument. Mr. Eldon Bankes appeared for the appellant, and the Justices were represented by an affidavit, which stated that a complaint was made by Hayton against Wilson Brothers for erecting a wooden stable in Redhead Street, South Shields, without submitting plans to the borough surveyor for approval, in accordance with the by-laws. Defendants were the owners of an acre of ground in Redhead Street, and they contended that it had never been the custom of the Corporation to require plans of a wooden stable to be submitted to them, neither had the by-law been insisted upon as being applicable. The Justices adjourned the case and inspected the building, and they then came to the determination that the by-law in question did not apply to a stable built of wood on enclosed ground, as in the present case, and they therefore refused to state a case for appeal.—Mr. Bankes, for the appellants, said the Justices must have viewed the wrong building. They went there on their own initiative, and now said the building they saw was in the middle of the ground, but that was not the case. It had an entrance from Redhead Street. This was an extremely important matter as far as the Corporation was concerned, because it had reference to all the buildings within their district. Counsel having quoted authorities, their Lordships made the rule absolute, calling upon the respondents to show cause why they should not be convicted.

Keystones.

Mr. Henry Littler has been appointed county architect of Lancashire.

A Church Pupil Teachers' College at Liverpool is to be erected on a site in Colquitt Street, at a cost of about £8,000.

A New Parish Church of St. Chad, Bensham, is being erected at Gateshead. The architects are Messrs. Hicks and Charlewood.

Mr. Holman Hunt has been presented by many friends and admirers of his art with his portrait, painted by Sir W. B. Richmond, R.A., and a silver salver.

Llandaff Cathedral has had a new organ added, and a memorial effigy of the late Dean Vaughan has been placed in a niche in the north aisle. The memorial is in main the work of Mr. W. Goscombe John, A.R.A.

Proposed New Town Hall at Workington.—A Local Government Board enquiry was held recently into the application of the Workington Corporation for the borrowing of £11,750 for the provision of a new Town Hall.

A New Test-House and Casual Ward at Manchester is to be erected in Tame Street, by the Workhouse Committee of Manchester and Chorlton in place of the late one, which was burnt down. The cost will be about £40,000.

The Permanent Building of the Free Home for the Dying, 29 North Side Clapham Common, S.W., has been dedicated, after considerable alteration at the hands of Mr. A. E. Street. The purchase of the freehold and the alterations and repairs have cost more than £10,000.

New Technical Institute, Free Library, and County Buildings at Newport, I.W.—At a special meeting of the Isle of Wight County Council held recently, the plans submitted under the motto "X" for these buildings were approved, subject to certain alterations as to drainage. The cost of the work will probably not exceed £7,900.

Housing of the Poor in Berlin.—The municipal authorities of Berlin have resolved to make a grant of 1,000,000 marks to be devoted to the provision of housing accommodation for the poor, in commemoration of the two hundredth anniversary of the foundation by King Frederick I. of the Prussian Monarchy which will be celebrated on January 18th, 1901.

Proposed Imbecile Home for Westmorland and Cumberland.—A scheme is on foot for the erection of an imbecile home for the counties of Westmorland and Cumberland. The estate would consist of 100 acres of cultivatable land with outbuildings upon it, to cost £4,000, six pavilions or detached houses to cost £27,000, or £90 per head, officers' apartments, &c., to cost £5,000, and a small sanatorium, &c. £3,000; total £39,000.

A School of Science and Art at Weston-Super-Mare has been erected at a cost of £4,000.

A New Church at Wycliffe Street, Southwark, to be dedicated to St. Bartholomew, is being erected at a cost of about £9,000.

All Saints' Church, Leamington, has had its nave enlarged, a bell tower added, and has been generally restored at a cost of about £18,000.

A New Episcopal Church at Ayr has been erected from designs by the late Mr. J. L. Pearson, R.A., at a cost of £10,000, exclusive of furnishing.

A Statue of the Queen, by Princess Louise, has been erected at the entrance to the Royal Victoria College for the Higher Education of Women, Montreal.

St. Mary's Church, Turville, near Henley-on-Thames, has been internally restored at a cost of about £1,700. An organ chamber and a new vestry have been added.

A Shelter and other Buildings at the City Mortuary, Golden Lane, E.C., have been erected at a cost of £11,000. The contractors were Messrs. E. Lawrence and Sons.

The Organ of St. Laurence Jewry, E.C., originally built by Renatus Harris, and enclosed in a case by Grinling Gibbons, has been restored by Messrs. Norman and Beard, of Norwich.

Nurses' Home at Lambeth.—The Lambeth Guardians have approved an estimate of cost, amounting to £59,915 17s., for the erection of nurses' home, new offices, relief station, observation wards, and alterations to the central administrative block at the infirmary, which will increase the accommodation by 100 beds.

A Stained-glass Memorial Window has just been erected in the Redlands Green Chapel, Bristol, from designs by Mr. T. W. Camm, of Smethwick, Birmingham. The work is Classic in treatment, and is in memory of the late Dr. Pritchard, F.R.C.S., of Bristol. The subjects are suggestive of the man and are three in number: "Our Lord as the Great Healer; "St. Luke, the Beloved Physician," and "St. Barnabas, a Son of Consolation."

The Wool Exchange, Coleman Street, E.C., is undergoing structural alteration for the improvement of Kohler's Restaurant, which occupies the whole of the front portion of ground floor and basement in this extensive building. The steel construction is being carried out by Messrs. G. Aston and Son, and Mr. Charles Heeps, of London Wall, is the builder. Mr. Francis Witt, M.S.A., of Manor Park, Essex, is the architect.

New Seamen's Hospital at Cardiff.—In order to prepare the site for the new Seamen's Hospital at Cardiff it has been necessary to reclaim land adjoining the Ferry Road, southwest of the *Hamadryad* ship. Mr. James Allan, contractor for the new Mount Stuart Dry Dock, has tipped some thousands of tons of black clay at this point, with the view of filling up the land to the level of the road. The weight of the embankments has forced up the soft mud, and the pitching which has been laid on the sea side has been disturbed, except on the eastern face. Mr. E. W. M. Corbett is the architect.

Finds at Kinloss Abbey.—In the course of some improvements and excavations recently carried out at Kinloss, under the direction of the Rev. J. A. Dunbar Dunbar, of Kinloss and Seapark, the workmen came upon the remains of several coffins of oak and pine, and a collection of human bones, in the rubbish lying in the old chapel. Underneath one of the coffins parts of a broken vessel were found, and among the rubbish several pieces of tiling with painting and ornamentation were picked up. These latter, doubtless, formed part of the back of the altar in the chapel. A communion token, an ancient key, and a piece of diamond-shaped glass, evidently from one of the windows, were also found. A large number of stones of fine masonry were unearthed during the operations. Certain portions of the ruined abbey, which are now in a precarious condition, are to be repaired.

COMPLETE LIST OF CONTRACTS OPEN.

DATE OF DELIVERY.		WORK TO BE EXECUTED.	FOR WHOM.	FROM WHOM FORMS OF TENDER MAY BE OBTAINED.
		BUILDING.		
Nov.	9	Calstock, Cornwall—School	School Board	H. J. Snell, Architect, The Crescent, Plymouth.

New Companies.

London Electric Warehouse Company, Limited.

This company was registered on October 25th with a capital of £1,000 in £10 shares to carry on the business of electrical engineers, electricians, suppliers of electricity, manufacturers of and dealers in electrical machinery, &c. Registered office: 78 Cheapside, E.C.

Diamond Anthracite Mine Company, Limited.

This company was registered on October 22nd with a capital of £20,000 in £1 shares to carry on the business of colliery proprietors, miners, fuel, brick, gas, coke, and coal-tar manufacturers, smelters, founders, engineers, &c. The first directors (to number not less than three nor more than seven) are to be appointed by the subscribers.

Stafford and Rogers, Limited.

This company was registered on October 25th with a capital of £8,000 in £1 shares (1,500 preference) to acquire the business carried on at Bedford and elsewhere as Stafford and Rogers, and to carry on the business of auctioneers, land, house, and estate agents, valuers, &c. The first directors are J. Rogers, C. C. Stafford, W. Kingston, J. A. Weston, and C. R. Craddock.

Standard Incandescent Gas Light Company, Ltd.

This company was registered on October 16th with a capital of £60,000 in £1 shares to acquire certain patents relating to improvements in the manufacture of gas mantles (numbered 2,000 and 15,500 of 1896) for the United Kingdom of Great Britain and Ireland, to develop and work the same, and as manufacturers of all kinds of gas-lighting apparatus and appliances. The first directors (of whom there shall be not less than three nor more than seven) are to be elected by the signatories, B. F. Simpson, J. Phillips, T. Baker, A. S. Dimsdale, A. David, H. Bartley and L. Goldstein.

British Electric Street Tramways, Limited.

This company was registered on October 18th with a capital of £300,000 in £10 shares to construct or purchase and equip electric tram and railroads, vans, carts, carriages, and other vehicles for the transportation of goods and merchandise of every description, passengers, &c., whether under the Hackney Carriage Act or otherwise, to adopt an agreement with the Electric Tram Construction and Maintenance Company. The number of directors (of whom there shall be not less than three nor more than eight) are to be elected by the signatories, F. Howard, F. Hopkins, O. M. Bolton, C. W. Murphy, H. J. Taylor, H. E. Hill and R. M. Albery. Registered office: 34 Victoria Street, Westminster.

Engineering Notes.

The Admiralty Pier at Dover is being lighted electrically by Messrs. Donnison, Berlyn, Sillem & Co., of London and Liverpool.

Ystrad Library, Glam., is being fitted with "small tube" hot-water heating apparatus by Messrs. John King, Ltd., engineers, Liverpool.

The Redheugh Bridge, Newcastle-on-Tyne.—The construction of a new bridge over and entirely clear of the old Redheugh Bridge is now approaching completion. The engineers are Messrs. Sandeman and Moncrieff.

London Water.—Small as is the hope they can base on the character of the new House of Commons, the Water Committee of the London County Council propose once more to bring in a Bill for the purchase of the undertakings of the metropolitan water companies.

Lighting of the Chapel Royal.—The Chapel Royal, St. James's Palace, is to be lighted in future by electricity. The new illuminant is in course of installation, and the work (which was interrupted by the preparations for Thursday's memorial service), is likely to be completed in about a week.

London Dock Lighting.—The new electric installation for the London and St. Katherine Docks has been completed.

Electric Traction and Scientific Observations. A meeting of the Board of Trade was held last week with reference to the regulations desired by the scientific departments of the Government in order to prevent interference with the delicate magnetic observations at Kew and Greenwich by the influence of electric traction.

A Large Gas Plant Contract.—The Edinburgh and Leith Corporations' Gas Commissioners have placed with Messrs. Graham, Morton & Co., of Leeds, a contract, amounting to £113,802, for the erection of a complete automatic inclined retort carbonising plant, including their improved system of elevating and conveying machinery for handling coal.

Proposed New Dock for Avonmouth.—After thirty years' fighting over the question of dock extension the Bristol Town Council have finally abandoned the proposed dock station of the river Avon, and, with a solitary opponent, have resolved to apply to Parliament in the ensuing session for an Act to carry out a scheme for a new dock at Avonmouth at a cost of £1,804,000.

Electricity on the Underground.—The Electrical Traction Joint Committee of the Metropolitan and District Railway Companies has fixed December 1st for the receipt of tenders from the electrical traction firms which have been invited to submit offers for the installation of electrical traction on the Inner Circle Railway. During the last few months the companies have been conducting an experiment in electrical traction on a section of their system at Kensington.

Improvements at Dover.—The Dover Town Council at its last meeting approved the scheme to construct a viaduct from the lower part of Snargate Street through what is known as the pier district to the south-eastern district, where are situated the Lord Warden Hotel and the Admiralty Pier. An expenditure to the town of over £100,000 will be involved, as will also an additional cost of £500,000 to the Harbour Board. The scheme also includes a space for a big joint station and for an improved goods depot, and means the clearing away of a large unsanitary area long condemned by the health officer. There will be a large rebate on the expenditure by a contribution from the amalgamated railway company, and this will reduce the cost to Dover itself to £45,000.

TENDERS.

Information from accredited sources should be sent to "The Editor." Results of tenders cannot be accepted unless they contain the name of the Architect or Surveyor for the Work.

ASTON MANOR.—For alterations to fire stations, &c., Chester Street, for the Urban District Council. Mr. G. H. Jack surveyor, Council House, Albert Road, Aston Manor :—

CONTRACTS OPEN.

PARISH of WILLESDEN.
TO IRON HOUSE BUILDERS.

The Guardians of the Parish of Willesden desire to receive TENDERS for the ERECTION of a Temporary IRON BUILDING for the accommodation of 30 infirmary patients in the grounds of Temporary Infirmary, Rockhall, Cricklewood.

Persons willing to Tender can obtain particulars of the requirements of the Guardians and a form of Tender on application to me, at my office as below.

Tenders, accompanied with plan and detail specification, must be signed, sealed, endorsed "Tender for Iron Building" and delivered at my office not later than TWELVE o'clock noon on WEDNESDAY, NOVEMBER 14th, 1900.

The Guardians do not bind themselves to accept the lowest or any Tender.

By order
J. HUTTON HAYLOR.
Clerk to the Guardians.

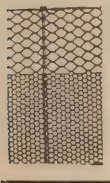
Guardians' Offices,
No. 329 High Road, Kilburn, N.W.
November 1900.

TO BUILDERS and CONTRACTORS.

The Guardians of the Woolwich Union require TENDERS for the ERECTION of TWO COTTAGE HOMES, a RECEIVING WARD, and OUTBUILDINGS, upon their site abutting upon Lodge Lane and Long Lane, Bostall Heath, Plumstead.

The drawings and conditions of contract can be inspected, and bills of quantities obtained, at the Office of the Architects, Messrs. CHURCH, QUICK AND WHINCOP, William Street, Woolwich, any day from the 7th to the 14th inst. (both days inclusive).

A deposit of £2 2s. will be required, which will be returned upon receipt of bonâ-fide Tender.



Tenders must be upon the form supplied and addressed to me, endorsed "Tender for Cottage Homes," by ELEVEN a.m. on WEDNESDAY, the 21st inst.

The Guardians do not bind themselves to accept the lowest or any Tender.

By order,
TOM CUTTER,
Clerk to the Guardians.

Union Offices, Woolwich,
November, 1900.

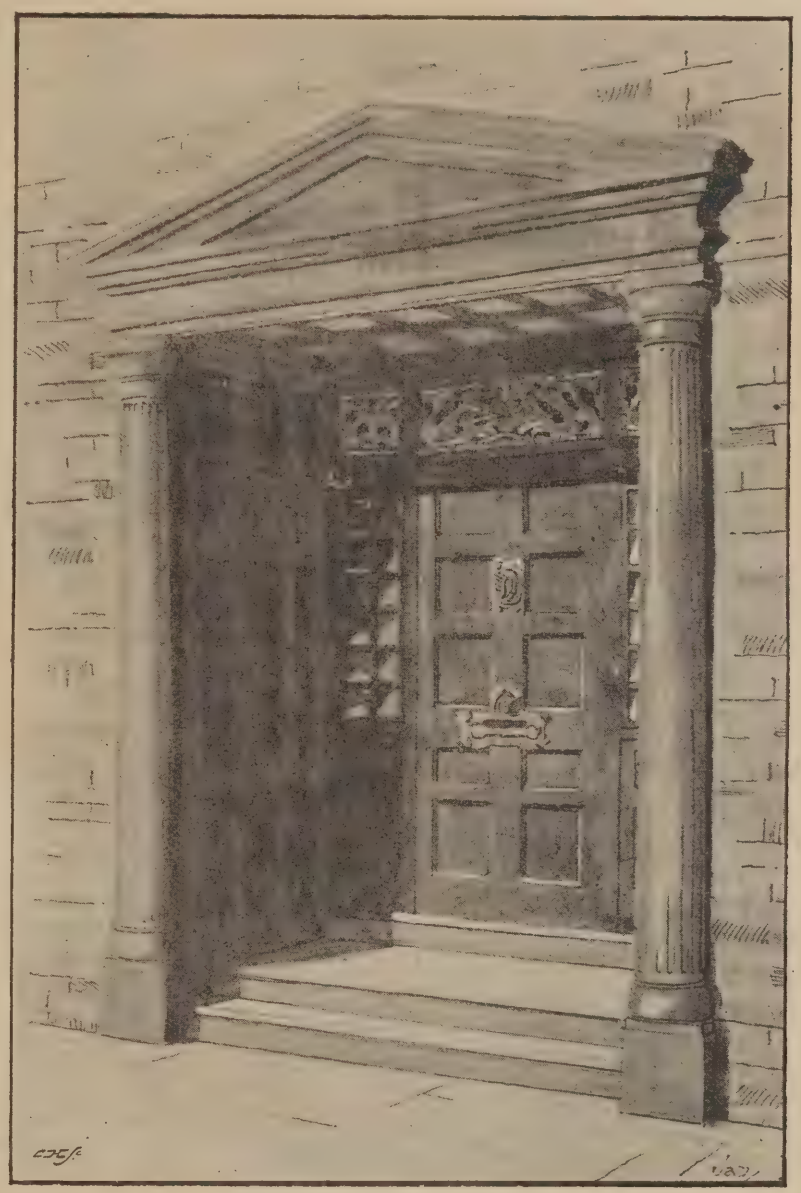
An Architectural Causerie.



"Render unto Cæsar."

That we are living in an age of draughtsmen seems to be borne out by the plain test of market values. In the assistant class it is the "good draughtsman" who can command a pay out of all proportion to his knowledge and experience, and to his possession of those qualities which would make him more than another a competent master of building. Who is the young fellow that can escape from the thraldom of being tied to one office, and as a free-lance can both make more money and have a better time? Who is it that can throw back his head and expand his chest, look dread principals straight in the eye and speak his mind freely to them; before whom the said principals, grey-headed men, place their poor sketches with all the hesitating diffidence of a first-year's pupil; who can arrange his own times and seasons, and take a day whenever he wants to do so; who can stay in his rooms when he will and draw perspectives or do "washing," or go for a time to this office or that, and average pretty nearly his pound a day throughout the year; who can be sure of a good autumn holiday, which he plans to suit his own convenience, and not that of the manager of an office; and who all the time may buoy himself with the reasonable hope that some day he is pretty sure to "pull off" something and burst on the world as an architect in fact? It is not the man whose judgment is the most matured, whose knowledge of material is founded on experience, whose strains and stresses are irreproachable, who is the most reliable business man, who, in short, has all the more solid qualifications. It is his showy brother of the ready pencil, the clean line, and the trick of using his brush, who can draw with "snap" and print divinely in many strange characters.

And how, on the other hand, is it with those who belong to the class of principals? Surely here again it is the draughtsman-architect who is the shining light. A great living master is reported to have said that he could get on quite well without any "fools of assistants" about him. Another great one, but recently dead, believed that the architect's own hand should draw every detail of the building. "No architect can attend properly to more than two works at a time, and," he would say "that is just one too many, only a man must live." The names of these two are names to conjure with, and the slight clues I have given will be sufficient for their identification by many. One could add instance to instance of this kind to point a similar moral, till one is almost forced to the conclusion that it is by the way of the draughtsman-architect alone that any good thing can come. It would seem to be only reasonable. The mind that conceives the work can surely best guide the hand that translates the conception into line and measurement. The more minds through which the idea has to pass on its way to paper the more must its crispness be worn away.

Yet that such need not necessarily be always the case is proved by another set of instances, in no wise so numerous, it is true, but none the less telling and credible. There is one in particular which recent years have brought to light that I should like to refer to. It is unfortunate that for reasons which I need hardly point out I am unable here to give names. This handicaps me necessarily with all but the few readers who will be able to recognise the persons meant. An architect, who is a truly great designer of buildings of an almost monumental dignity, the soundness, thoroughness, scholarliness, yet withal the individual vigour of which will keep them alive when most of our contemporary work has been dismissed from men's minds with the forgotten "plates" that illustrated it, was known by a few to be one of those who *do not draw*. In and about his office, in what actual capacity I know not, but presumably as his chief draughtsman, was one of the cleverest of the younger men in the profession, and to his credit (in spite of his own emphatic disclaimers) was frequently laid the excellence of the master's work. Yet that clever draughtsman is now in a practice of his own, a draughtsman-architect among the best of them, and in his old place another reigns—that other a man trained in a completely different school, though in his way none the less able. Now here comes the circumstance which gives my instance its point. The work which comes from the office still maintains its excellence, and more than that, its subtle individuality. This seems a strong proof that the hasty judges of our architect were wrong, that he himself and not his draughtsman has all along been the man whose was the mind to conceive and direct what the hands of others but carried out. The above is only one case in point. Let us take another, that of the architect of numberless beautiful churches. It would surprise not a few to hear that the author of such exquisite work, this master of lovely detail, draws hardly at all except in a kind of crabbed shorthand to be understanded only by the expert.

So then there are two sorts of architects, those who draw and those who do not draw,

DESIGN FOR A FRONT DOOR. BY E. S. HARTLEY.

and we may take it that both do good and bad work irrespective of whichever class they belong to. We need not attempt to say whose is the better method, or even that one method is preferable to the other. It may be that those of one class draw because they have not the faculty of imparting their ideas otherwise, or in default of capable assistant-draughtsmen, and that those of the other class do not draw because their practice is so large that they have not time for it. But we do wish to protest in the strongest terms against the very common fallacy that it is impossible for a man who does not draw to produce good work. To produce it, that is, not merely as principal of the office from which it emanates, but out of the personal exercise of his own creative faculty. The fallacy is particularly common amongst assistants and young architects, even amongst the very young fellows who are engaged in drawing out the non-drawing architect's work. They are rather apt to pose as the actual authors of it. Such a feeling of creative possession does it give to draw a thing in the spirit in which it ought to be drawn, that it is almost inevitable that this should be so. Indeed, it is quite right and proper, for, as I say, the feeling of having created comes naturally from the draughtsman's having so entered into the spirit of what he has drawn as to have drawn it as it should be drawn. When you have finished your sketch of Gloucester tower, you should feel as if you had just designed it (or all of it but that clumsy expedient at the corners of the parapet), and not old Abbot Seabroke 450 years ago. Even when you have finished copying your orders out of "Chambers" you should feel as if you were in truth their designer. But you should be very careful, while indulging this feeling to the utmost, frankly to recognise that it is a somewhat fallacious one, and apt to set light heads a-swelling, and loose tongues a-boasting. It is thus that "ghost" stories get about. My friend, it is a beautiful drawing of Gloucester tower you have made, but you will not forget who really designed it. Then have the frankness to own also that it was not you who designed Mr. X's beautiful Newgate Street elevation, which you also drew. Mr. X may be magnanimous enough to allow you to continue in the idea that you did design it. He himself knows better. But the public does not, and the public is apt to believe what it is told. Whether it believes it or not, if you ask it to, look at the position in which you are placed. You are either a humbug, or you are serving one. You are either a humbug or a "ghost," an unsubstantial being who has sold himself for a few pounds a week.

J. B.

The Unity of Arts. At the last banquet of the Sculpture Society of America, Mr. John La Farge, speaking for the Society of Mural Painters, said, somewhat sarcastically: "We cannot teach the architects because, officially, they know more than we do. A young architect of twenty-one knows more than a painter of seventy. What we want is a man conversant with the three arts (painting, architecture and sculpture) practising one, but in sympathy with the others. It is for the extension of that feeling that our society is founded." If the last statement is true the mural painters are false to their trust, as such expressions as the one quoted are certainly not productive of a better understanding between the men who practice the three arts referred to. Whatever the shortcomings of the architectural profession at large may be, it is unquestionably true that the average cultured architect is more conversant with the part that both sculpture and painting play in his art than either the painter or the sculptor is with architecture.

A. M. T.

On Reflection.

Baths for the Poor. We are glad to find that the proposal of Mr. W. R. Court, engineer and chief superintendent of baths at Liverpool, for providing baths for the poor (a proposal discussed in our issue for September 27th, 1899) has been so far developed that a Local Government Board enquiry has been held into the Corporation's application to borrow money for the purpose. The scheme is to erect on a site immediately adjoining the docks a building in which would be provided a large number of rain or shower baths, and a certain number of slipper baths. As we have already pointed out, for the working classes—people whose employment makes them very dirty—there can be no doubt that the shower bath is the best possible arrangement, for it cleanses the bather from head to foot and carries away the soiled water at once; whilst, on the average, less water is needed than for slipper baths, and it is possible to reduce the charge for admittance. At Liverpool it is proposed to make the charge as low as one penny. It will be possible to have a hot or a cold spray, as desired, though, as the temperature of the water will never exceed 90°, there will be no danger of the bather scalding himself. In Germany, Austria, and America this system of cheap baths for the people has been practised with much success, and we hope that the Liverpool scheme will receive the sanction of the Local Government Board. As a nation we observe a singular reluctance to adopt new methods or systems; this has been the case in regard to technical education; but we now find out, to our cost, that the old idea is too limited, and it is therefore some consolation, now that our eyes are opening a little, that we see the foolishness of a studied complacency.

Street Regulations. In June last a conference was held between the London County Council and the several local authorities of the metropolis with regard to certain street regulations, and a committee was then appointed to report on the decisions which were arrived at. This committee submitted its recommendations at the adjourned meeting of the conference held on Wednesday last, and it is to be wished that those which were adopted will be carried into practical effect by the central authority and the new Borough Councils. The present condition of the streets is most unsatisfactory, for not only is it the custom to constantly tear up the surface in order to lay or repair gas, water, and other mains, but there is no thorough and regular cleansing. The conference recommends that all streets paved with asphalt, wood, or granite setts should be well washed after sweeping; a system which, though extensively adopted on the Continent, has received little attention in this country; it is the only way in which the streets can be effectively cleansed. In this particular the asphalt roads are especially suitable. Leadenhall Street (asphalt) is an example of proper and systematic cleansing, while the Euston Road (wood) is a standing disgrace because of the filthy condition in which it is allowed to remain. As to the Embankment, despite the thousands of pounds which have already been spent in the endeavour to produce a proper surface, no satisfactory result will be obtained till wood or asphalt replaces the present macadam. We agree that greater supervision of the scavenging is absolutely essential to secure the efficient cleansing of the roads and footways of the metropolis. The mud at present thrown up by passing vehicles is of a most objectionable kind. Another recommendation which has received the approval of the conference is that the section of the Public Health Act, 1891, compelling local authorities to remove snow from the footways should be repealed. This means that householders would have to clear away their own snow. But as local authorities have hitherto been singularly lax in performing the duties imposed on them by the section in question most householders would not notice the change. There is, no doubt, force in the argument that the authorities of the many towns which form London already have their hands full with the cleansing of the roads, one district alone having 124 miles of streets to look after. But it is properly the duty of the local authority to keep its streets and pavements clean. Naturally there was a recommendation that all wires and pipes should be placed in subways; but this very necessary reform has been so often pleaded, so often approved, and so seldom carried out, that one tires of its advocacy and wishes that authorities would face the large initial expenditure once and for all, enabling them to keep their roads in a proper state, and getting rid of a great source of inconvenience and annoyance.

The Marble Arch. It has been rumoured that the famous Marble Arch designed by Nash is to be removed, but we see no sufficient reason for such an act. In 1827 it stood opposite Buckingham Palace, and was afterwards placed in its present position at the north-east corner of Hyde Park; it has become a London landmark, familiar to all visitors and always of interest to Londoners, and it would therefore be a pity to take it away. If it is considered out of place, probably Decimus Burton's screen at the opposite side of the park will be considered similarly out of place. But we think both are well situated. There is one matter relating to the Marble Arch which is more worthy of consideration. It is that some sculpture should be placed on top of the Arch: this was the first intention, and the equestrian statue of George the Fourth now in Trafalgar Square was intended for the position. As the Arch stands at present it looks more incomplete than out of place.

Berlin's Housing Problem. It is now becoming generally understood that almost every city has the dread housing fiend to grapple with. Bombay has a huge problem; Paris is, perhaps, too light-hearted to unduly trouble herself about such matters; but at Berlin the question of providing houses for the poorer classes is assuming an alarming aspect. In the opinion of General Booth, who was recently in the great German capital visiting his wonderful organisation, though Berlin outwardly looks less destitute and the new tenements are larger than those we are familiar with, the conditions under which the poor live are very distressing, and nothing is done to prevent tenants taking in lodgers, a practice which is very common and very deplorable. Two reasons for the present dearth of dwellings are that the land in Berlin is freehold and is enormously increasing in value. The magistracy of Charlottenburg has decided to offer municipal land at cost price to a building company for the erection of dwellings for workmen in the employ of the municipality, for officials and for school teachers, and the city has started with £50,000 a fund for providing houses for destitute and homeless families. This would be considered too socialistic in this country.

THE CHURCH OF NEWTON NOTTAGE. DRAWN BY R. MORTON NANCE.

THE CHURCH OF NEWTON NOTTAGE, GLAMORGANSHIRE.

BY R. MORTON NANCE.

THE old church which forms the subject of the accompanying sketches lies within a few hundred yards of the Severn, and in days gone by the weather-beaten tower, with its saddle-backed roof, was no doubt a welcome sight to the mariners who braved the perils of Sker, Tuskar, and the Nash (names suggestive of angry seas and rending planks) to run their ships up on the beach which formed the port. Since many years, however, the ships have deserted to a newer harbour a mile or two away, which, in its turn, is falling behind in the race that has made such hives of activity of the seaports most fortunately placed to tap the South Wales coalfield; and now the only relics of the former status of Newton Nottage as a port are some disappearing mooring-posts on the beach, and the inn sign of "The Jolly Sailor."

Of the past, too, buried in the sandhills that have been blown up by the Atlantic gales, is a great part of the village, where from time to time the shifting sand discloses the ruined walls of houses. The last great inroad of the and took place, as we are told, in the early years of the sixteenth century, and although the frequency of neolithic remains in the sands shows that it has not been altogether the work of a few centuries to pile up these mountains of sand, there is no doubt that a vast portion of arable land and many dwelling-houses were then overwhelmed.

Close to the church, with its water protected from sand by a hood of stone, is the ancient well of St. John the Baptist. It stands at a corner of the village green, and, according to the set of the tide, is either the resort of the villagers with their pitchers, or left to the cackling regiments of geese that evidently consider the place their own; for the spring has an outlet above low-water level, and the propitious time to obtain a supply of the sacred fluid is just after the turn of the tide from flow to ebb, which has given rise to the idea that it ebbs and flows contrary to the sea.

Near the well were lit the bonfires on St. John's Eve which were expected to strike terror into the hearts of the foul dragons that, according to popular belief, spoilt the good water of the well and brought death to the drinkers thereof.

The dedication of the church is also to the Baptist, and a head carved on a projecting stone near the top of the tower is supposed to represent that saint; while the fact of St. John having been chosen as their tutelary saint by the societies of flagellants would no doubt account for the subject of the carving on the stone pulpit, which represents the flagellation of Christ in a remarkably quaint and archaic manner. Two grim-visaged men, in mediæval costume, hold either end of a most substantial cable which is knotted round the feet of the central figure, and raise in their right hands most murderous-looking knouts. Upon the canopy above are carved two weird angels bearing, apparently, a cup, although its shape is sufficiently vague as to have allowed it to be considered an hour-glass.

To enter this strange pulpit with dignity requires some little practice; for it is approached by a small flight of stairs winding in the wall, and the arch leading into the pulpit is so low that to walk upright is to court disaster. The same doorway in the wall gave access to another flight of steps, leading to the rood-loft, long since demolished.

The carving of the whole pulpit is so rude as to have suggested that, with the font and the south porch, it was a legacy from the earlier church that was built here in Norman times; but there can, I think, be no doubt that it is work of the fifteenth century, when most, if not all, of the existing church was built. The carving on the exterior of the church is exactly what might have been expected of the same man when something less ambitious than figure work was demanded of him—the angels and foliage all have a species of family likeness. One likes to imagine him a local self-trained stoneworker, with an excellent idea of proportion and general effect, working out his ideas in his own way. At Candleston, a few miles across the sandhills, is a beautiful old perpendicular fireplace, which seems to be the work of this same craftsman.

By whomsoever produced, it is very interesting work and full of energy and character. The whole building, indeed, owing partly, perhaps, to its situation, has an air of dis

THE PRIEST'S DOORWAY, NEWTON NOTTAGE CHURCH. DRAWN BY R. MORTON NANCE

tinction and personal charm. It has suffered a little from the restorer and improver at different times. The old stone roof has gone, and most of the windows have been replaced.

The Rev. H. H. Knight (who, in his book on this parish, written in 1853, did so much to preserve old memories), mentions a saint's bell-turret at the south-east corner of the nave, and on the wall below it, a fresco of Adam and Eve, both of which had even then disappeared.

But in spite of modern improvements, the old tower, with its beautiful doorway, still stands double-buttressed against the westerly gales, and bids fair to do so even when the old prophecy is fulfilled, and ships are moored to the tree above it, when the sea returns to cover the sands.

THE REVIVAL OF GOTHIC ARCHITECTURE.*

By HALSEY RICARDO.

UNTIL the dawn of the fifteenth century after Christ the art of architecture had been one continuous art that had grown from the actual needs of the people who were developing it. Unlike in appearance as Egyptian, Greek and Roman architecture are to Gothic, they are alike in respect to their origin and the purpose that breathes through them.

What was wanted was provided in the frankest way from the materials nearest to hand, the behaviour of the materials was watched and analysed, and the experience gained was made the stepping-stone to further progress and new applications. Out of the materials themselves, their requirements and their humours, came the design—their failure showed them the limits of their constructions in one direction, whilst it showed them the possibilities in fresh.

The Romans, for example, dowered with a natural cement, found at the time the Cæsars were establishing the Empire, and when their expansion and prosperity grew with most amazing rapidity, that they could build with greater ease and with less time in concrete than they could with wrought stone, and following on this they soon found that they could build in their new material far larger and more adventurous edifices than they could dream of attempting in either stone or brick. So, too, the mediæval builders discovered, observing how their walls gave way under the pressure of their vaults, that if they strutted these walls at the proper positions with raking shores they could balance their vaults how and where they liked and, where desirable, do without the intervening spaces of masonry—and thus we arrive at the Baths of Caracalla and the Cathedral of Amiens.

Architecture was a growth—varying, according to the nature of the soil it found itself rooted in, in its outward appearance—modified from time to time by fresh grafting as the nature of the passions and ambitions changed under which it grew; but the growth was straightforward, the sap coursed along its natural branches, which spread out and ramified into special groups of foliage and highly complicated blossom; it stood with its roots in the deep past and its topmost branches aspiring to the zenith.

The revival of learning, which brought with it the revival of the arts, converted this tree to a pollard, checking its natural growth. For a time there was so much life in the plant that it threw up fresh thickets of branches and saplings—but the pruning-hook of learning and the withies of taste were for ever checking and directing the sprouts, so that gradually life faded away from the trunk, and grubs and beetles built in the wood of it, where before birds had nested in its leafage.

Hitherto architecture had been spontaneous; it now became self-conscious. Mediæval architecture was the expression of a popular enthusiasm for building which went hand in hand with the piety of the people; it was popular and it was sincere.

The architecture of the Renaissance was individualistic; it was not popular, it was infidel and insincere. Our mediæval churches and cathedrals were raised by guilds of craftsmen, assisted and furthered by the people around them. Stones and timber were hauled by amateurs, in their enthusiasm, money was collected by self-denying ordinances, for the aggrandisement of the monuments they were raising in their city. What was novel in the outcome of their structures had its origin in what was familiar; it might surprise by its strides in the line of development, but it was always intelligible.

By the time of the fifteenth century the elements of weakness had already appeared in the guilds, and when the Renaissance took them over as a going concern it found them highly specialised, with a tendency to individualism disintegrating them. Still they had in them such stores of knowledge, experience and discipline as took centuries to dissipate. The leading sculptors, painters and architects of the Renaissance had been bred up in the shops; they knew what could be done with the materials under their hand, they knew what the standard of excellence should be and what the standard of adventure. The decay that was bound to come, came slowly; at first there was no evidence of it at all; the fund of tradition was copious, and the leaders of the new modes of expression came from their own bands of fellow-workers and still worked amongst them. But they spoke a strange language: they came back from their travel with sketches and measurements of things long gone to ruin, of things alien and hostile to their modes of thought. To recall the Augustan age of literature and architecture was to the ordinary mind an uncalled-for phantasy, and to the religious mind an offence.

Architecture became dependent upon great patrons who supported it from without, when it had previously been inspired from within, and with this change all the arts became an inexplicable cult for the rich and the leisured—the craftsmen only co-operated in ignorance and without heart. Puzzled and checked by the exotic nature of their instructions, they relied more and more upon the oracle's guidance, their sense of responsibility in the matter lessened; and the fund of tradition was not only obscured and confused, but dwindled from want of concert. As architecture grew more learned, more correct, and more pedantic it grew more frigid, more wooden, and more wearisome. New styles were evoked to touch the jaded senses; men travelled farther and farther afield—all Italy was ransacked. Robert Adam journeyed to Dalmatia: Greece and Syria were reached. But other influences were on foot. Toward the end of the eighteenth century the doctrine of man's brotherhood to man had proclaimed—and then asserted—itself: a new spirit was astir and so potent that it changed, with us gradually, in France with violent upheaval, the bases of society.

New modes of thought showed themselves in poetry, literature, and subsequently in legislation. Closely following on this came the welding of England into one unanimous single-handed defiance of Napoleon, and—the contest decided—the great expansion of our influence and our commerce. The old social boundaries were either enlarged or broken down; the tolerant satisfaction or the weary acquiescence

*Paper read before the Liverpool Architectural Society on November 5th, 1900.

THE STONE PULPIT, NEWTON NOTTAGE CHURCH. DRAWN BY R. MORTON NANCE.

in things as they were was flung away, and in the passing of the Reform Bill men thought that a new era had dawned and that again there would be the vision of Astraea Redux. But in this upheaval of the old landmarks and solution of old ties many looked back fondly on the past and tried to find in the glamour of romantic history a compensation for the hurry and scramble of the present. They tried to lead two lives—by daytime they were in the toils of the nineteenth-century wielding and controlling the new forces of steam and electricity, with this great globe of ours hitherto immeasurable, with huge continents of unknown and fearful country, now shrunk to a measurable sphere, surveyed and explored, and traversable both safely and punctually—and then after business hours they surrendered themselves to the Wizard of the North and steeped themselves in the romance of the Middle Ages.

The Church, roused by the new temper and bade put its house in order, heard the summons, and obeyed. Whilst the Tractarians were devoting themselves to the examination of the sources of church authority and church discipline, the Camden Society set itself to investigate the authorities for its ritual and the history of its buildings. It was natural when trying back to turn to those periods when faith was strongest, emotion most creative, and passion most intense. The world of Religion and Art gazed back hungrily to the thirteenth and fourteenth centuries and proposed to set their house in the order of that time. But in this Gothic Renaissance there was this essential difference —there was no help from the craftsmen. When the first Renaissance flooded the land, it found the guilds in active life, and it took them over, with their traditions and their craftsmanship, and though it diverted them from the accustomed channels, the divergence at first was one of detail more than of principle. But the Gothic Renaissance found no such band of workmen to incorporate. Tradition there still was, though greatly starved and weakened—but, such as it was, it appeared to the Gothic architects incompatible with the New Gospel in Art, and the action of the Gothic Revival was to stifle and quench the few sparks that still lingered. The sudden reversion to the methods of workmanship of the Middle Ages was a new perplexity to the worker. While, on the one hand, in his shop, he was coming into possession of extended powers of machinery and appliance, he was bidden to put them aside for the new doctrine, or else make his machines simulate hand work. No wonder the Gothic Revival seemed to him a mere fashion, an affectation, and that architecture itself was a mystery and a creed that had its fashions and shibboleths; and, based on no actualities either of needs or the properties of materials, had no principles nor sense in it, but must be done blindly according to the instructions. Work done under such conditions must necessarily be tired weary stuff; the workman's criterion of excellence was inapplicable as a standard to the supposed mediæval temper, and he had no other—puzzled and disheartened he set himself doggedly to his task, to do his day's work loyally, but mystified, and in the end indifferent as to the purpose of his labour. Meanwhile the Revivalists, in the full industry of their zeal, proceeded, by the bitter irony of circumstance, to destroy the evidences of the style they were labouring to reproduce by every means that knowledge and feeling could give them, Gothic buildings were overhauled, furbished up, and restored throughout the land, so that more ruin was done by fifty years' attention to our examples of mediæval construction than the neglect of centuries had been able to accumulate. The work of the restorers did not pass without protest by those who more fully understood in what the nature of true Gothic consisted.

The foremost, the ablest, and the most eloquent of these was Ruskin, whose teaching had a power that might be denied, but could not be disregarded. Into the cause of Gothic architecture he threw the weight of his knowledge, his observation, his analysis; he met his opponents on their own ground, and the force of his logic stripped the facts of the case bare; to take a lower line of argument than his was to write oneself down as merely selfish and worldly; to rise to the higher level and attempt to contend with him there was a flight few attempted. He defined the nature of Gothic architecture in words no other man could have used, and which, despite the weight of the whole architectural profession arrayed against him, in the end prevailed. But the end was slow in coming, and meanwhile most of the important Gothic monuments disappeared under the process of restoration.

THE SOUTH PORCH, NEWTON NOTTAGE CHURCH. DRAWN BY R. MORTON NANCE.

Ruskin preached a doctrine difficult at that time to accept; and when the Oxford Museum was built avowedly in conformity with his teaching, and embracing the principles that he had enunciated, its failure, or partial failure, in the direction of beauty expected from it, helped to confirm the impression that Ruskin's doctrine was impracticable. But, as he pointed out, how can we expect the workmen of to-day to match themselves against the craftsmen of the past, when for the past three centuries we have been training them in other methods, cramping their individuality and discouraging their research and turning our backs on the inheritance that was the mediæval builders'. Such craftsmanship as theirs can only be acquired by the same slow methods under similar apprenticeship.

Of the architect leaders of the Gothic Revival, the men who seem to me to have had the foremost place in bringing about the Revival, and whose work was vitalised by their passion and sincerity, are Pugin, Street, Burges, and Butterfield. Before Pugin's time, broadly speaking, such Gothic architecture as was being produced was Gothic in seeming only. That the author of the "Waverley Novels" should inhabit a Gothic structure at Abbotsford was but proper, nay, it was almost incumbent upon him, as well as consonant to his taste, and Mr. Blore, his architect, was ready to fall in with so amiable a whim; so various territorial magnates considered that it was due to their ancestry that they should be living in middle-aged castles, and therefore transformed their Georgian dwellings into battlemented and machicolated imitations of the defences of the Barons when war raged throughout the land.

But with Pugin a far deeper note was struck. The Gothic Revival with him was a matter of conviction—strong as life, deep as death. For him the Middle Ages contained the true gospel, the Roman Catholic religion, the true faith. He set himself to reproduce the conditions of past time, old methods of life, old methods of construction. He saw well enough that to effect this properly he must reproduce the mediæval workman, and so far as he was able he established workshops and schools in which to train his men. We see now that this recalling of the past to serve as the present was a fond dream. It was not so evident then. At the back of the artists of the Gothic Revival was the great bulk of public opinion sympathising with them and strengthening their hands. Moreover, in his churches and convents he was providing for the survivors of the Middle Ages, for men who lived and worshipped much as their ancestors did.

So far as the conditions of the case could help him, they did; but his red-hot enthusiasm prevented his seeing how special they were. His restless activity forced him into polemical writing, enthusiasm winged his pen, zeal barbed it. He set himself to convince his hearers that the Gothic style, besides being

national, was the only rational style, and in consequence economical, and his patrons compelled him to make his words good. His great knowledge of old work forced him to see the glaring discrepancies between that work and his, but he had his excuses; the money, this time, would not permit sturdy walls and a stout roof, but the next time that should be amended. He undertook far more work than mortal man could manage, but he meant to have breathing time by and by, and the work meanwhile was of immense use in educating his workmen. His enthusiasm was contagious, and the schools he founded endured for a generation after his decease.

His knowledge was prodigious and his memory tenacious; he had a great facility in draughtsmanship, and his learning and his pen carried him into positions that could not honestly be realised. To us now, with our extended sources of information, his learning does not appear so colossal, whilst the substitutes and imitations of the real effects that he was trying to reproduce abate in us something of our esteem for his sincerity. But through his work breathes a spirit of lofty piety that kindles and purifies what he did. The work of an ardent beautiful soul, it stands, a possession to us, the record of the ferment and the passion of the mid-century, and made valuable by the quantity of noble feeling it contains.

With Street the case is somewhat different. He, too, was passionately in earnest, and his enthusiasm carried him impetuously into numerous undertakings. But on him was thrust, to a much greater extent, the weight of modern conditions. The churches he built were for reformed congregations, and though he and his school of thought tried to some considerable degree to ignore these reforms, yet there was much that had to be accepted. In his mind he recognised this, and desired to accept it loyally, but the spell of the past was upon his heart and his terrible facility with the pen carried him beyond the limits that he had appointed to himself. The gift of scholarship, the stores of his memory, stayed his hand where the conditions of the case required him to be creative; the attempt to recall features that once had life and bid them live again, because they were endeared to us, showed itself, for instance, in the Great Hall of the new Law Courts. When that design was clubbed and bludgeoned down by the Government of that day into less than half the area that it properly and originally demanded, it was clear that the attempt to preserve the hall was a fond one, and that in good sense, the hall should go. But a fine hall is an idea that speaks to every one, still more to the connoisseur, and most of all, to the architect. The hall was built to the cruel detriment of the comfort of the courts, the great vaults hang over it, gloomy and deserted, it was his heart's darling whilst he lived, and now that he is dead it serves mainly to guard and enshrine his monument.

With William Burges we have another temperament, and, in the main cast of it, far more mediæval. Not lacking in earnestness, and with a scholarship fully as ripe as that possessed by either Street or Pugin, his learning sat more easily on him, and there is a kind of sunny laugh in the buildings that grew up under his hand. He carries us back to the days of the Decameron, and puts one amongst Bocaccio's audience, and one is startled to find how vivid and real the dream is. He picks up the tools of the mediæval craftsman, with an echo of the laughter of hundreds of years ago, and works his stone with so convincing an air and with so much humour that it surely must be quickened into life. Burges had the power of transfusing himself amongst his craftsmen. His sculptors and painters kindled at his ideas and played up to him. All through his work you see not only the evidence of his feeling and his imagination, but also the pleasure of the artist-workman. There is great animation and romance in what he does, and we hurry along almost in breathless amusement as we follow him in his work. He tells us stories of doughty deeds and perils escaped, of damsels under enchantment, of wizards overthrown: we have Ivanhoe and the Talisman over again in terms of stone and painting. The days of knight-errantry are to come back again—ah! if they only could! Nevertheless, Burges' influence was a curiously impressive one: with all his devotion to, and scholarly application of, that particular period of mediæval work that struck his fancy, he was able also to incorporate the poetry of his time that he felt, and to show that architecture, saturated with his romantic personality, had a nearer kinship with the models he was copying than any other individualist's work, because of the glow of human feeling still warm in it.

The last name that I shall deal with to-night in connection with the Gothic Revival is Mr. Butterfield's, and it is his special and lasting merit that he was more than a revivalist architect—he was an architect in the wider and fuller sense of the word. He saw clearly and accepted loyally the conditions of the times in which he lived, and his structures embrace them frankly and cordially. He had studied the mediæval buildings with a closer and deeper analysis than Pugin, and with a greater reverence than Street, and he set himself to build for the necessities and ritual of the present day, using the Gothic vocabulary as his mode of expression. He was called by his own contemporaries, and himself accepted the designation of, Gothic architect, but his masterful individuality was poles asunder from the Gothic temper. Except so far as they appreciated and respected his knowledge of his materials, there was no co-operation from his workmen—everything was settled before the work was begun—down to the last detail, and no growth was permissible beyond what had already been foreseen. But he knew his materials well, what they had done and what they could do, and throughout his work they have a contented air widely different from the usual tired look that most walling has. How should it be otherwise under the present conditions of work? What does the mason of to-day know of the history of the stone as it lies on his bunker? What does he know of its behaviour after it has left his hands? The stone has come from miles away from a quarry he has never seen, and it is going to be set in a job miles away, which he will never see. Beyond the pride of doing his work truly according to the details given him, he can take no pleasure in his work; he has no scope for his own pleasures, his prejudices, his knowledge, and his work looks weary and mechanical, reflecting his own mood. It is a searching testimony of Mr. Butterfield's true feeling for his materials, and sympathetic prescriptions for their handling, that his buildings have a happy smile about them, as if they enjoyed being there. And this is gained, not by affected construction, not by any attempts at the sentimental and the picturesque—his buildings are not meant to appear as survivals, somehow hitherto overlooked, of the Middle Ages; they are planned for modern purposes, built of modern materials in modern methods, and everything is sound and durable about them. And in and through them all burns his deep sincerity. A man of strong convictions, and perfectly fearless in consequence, he heaped up his masses in simple logical answer to the requirements set him, and they became in his hands solemn, romantic, pious. There is nothing wayward, exuberant, or exotic about his work; it is the outcome of a quiet deep mind, not easily troubled, not easily influenced. To the great questions of his time he had made his answers, or else stood aloof; in his own craft he had trained himself so thoroughly as to be beyond the reach of doubt or misgiving; simple-minded, and in the true sense humble, he knew what it was to be a master in his art, and, unvexed by the perplexities that assail the most of us and strong in the fervent religious feeling that surrounded him and added to his own, he spent on his buildings the gift of an earnest soul fulfilling its appointed duty. That intense conviction, that sympathetic support of the many feeling and working with us, is ours of to-day no more. That the Gothic Revival would prevail and sweep all before it, as soon as its merits had made themselves known, was never doubted by Pugin and the men of his day. They looked forward to all England accepting the Gothic style as the recovered vernacular, and that whereas at the outset of the revival the tradition had to be made anew, they hoped that in course of speedy time their individualism would be merged and absorbed in the general growth of the style. It was a fond hope. By their enthusiasm, by their learning, by their sincerity, they produced buildings of taste—as we are doing still—but it is the Art of Taste, not the Art of Architecture. We must look elsewhere if we want to see living architecture, living and growing. We must consider what are the themes that touch the national conscience, the successes and powers that we pride ourselves in. We must recall the determination that England came to in mid-century, that if there must be poverty amongst us, at least it shall not go ignorant and diseased; that the afflicted shall be soothed, the industrious encouraged, the feeble protected. We turn to our schools, our asylums, our hospitals and our libraries, and we find a living architecture there. We pride ourselves on the great forces that we have harnessed to do our daily work, our railways, our shipping and our fleet, and we find in the harbours, docks, and the great railway arches that stride across our roads and waterways an architecture that is growing, because it is real and living. And paradoxical as it may sound, it is architecture so long as it is frankly constructive and to the purpose and does not affect the trappings of a past style or allow itself to be diverted from its proper ends to conform, or modify itself in a self-conscious effort, to some supposed standard of beauty. As soon as the engineer attempts to invest his building with architectural detail, he introduces an element that is exotic and artificial. Some day, let us hope, his work will gather strength and sprout naturally into ornament and beauty—the beauty that is born from the wise use and distribution of the materials and quickened by the workman's feeling that his work has been done well and his pleasure in the doing. For the present we must content ourselves with the bare bones of our art, viewing our requirements frankly and squarely in the face, tabulating and systematising our knowledge in construction and extending our powers in that line with the utmost experiment of research; and so using our knowledge that the work that has to be done may be done simply and straightforwardly and that the craftsmen employed may help to further our work by recognising the drift and sensibility of our purpose, and consequently, by their appreciation, advancing our ideas a step. Where the men are interested, there their work becomes interesting, and that is the quality we want our buildings to have.

Instead of being dumb masses of dead scholarship, the shrines of habits and thoughts of a world long since passed away, our buildings will speak to us of our aims and our shortcomings, and whilst we resolve to ennoble the former, we may trust with our fuller knowledge to lessen the latter.

Life to-day is greatly different from the life of the eighteenth century, and the architecture of our day, do what we will and protest how we may, shows itself in exact response to our mode of life. Like puppies, we find ourselves in possession of huge paws, and we have not as yet grown up to them. Our proportions are as yet immature, and we are incessantly being measured by the standard of the full-grown races that have preceded us. Unlike puppies and too experienced and saddened to be child-like, we allow ourselves to be over-much troubled at the awkwardness of our figure and the clumsiness of our gait. Painfully self-conscious, each sprawl disconcerts us, and we aim at standards of deportment that are beyond our years and alien to our dispositions.

One feature of the present time is our feeling for corporate action and corporate life. Our knowledge which has taught us to annihilate space and time has not made us happy, but it has brought us sympathy with those around us, and given us charity. Our world is infinite no more—but the definition we have gained, has not brought us either conviction or comfort; doubt and perplexity runs through what we do, and what we think, and reveals itself in our art,

which is the reflex of men's minds. With the world to choose from, never before was self-consciousness so eclectic and its choice so crippled. The canons of taste are now clamouring for simplicity, showing how tired we have got of the trappings and upholstery of past styles, and how insufficient they are to hold our interest after their novelty has worn off; and in this simplicity lies our hope that we may touch the heart of things, take our problems frankly and loyally, and try to work them out in common sense, using our knowledge of construction to further our powers of design, not to cramp them by enabling us to raise buildings of impossible appearance; and our knowledge of what has been done in past time to be our guiding spirit in respect to the aims, the methods and the piety of the master builders—our forefathers.

WATER ENGINEERING.

ON Tuesday in last week the Institution of Civil Engineers opened its eighty-second session. The new president, Mr. James Mansergh, in the course of his inaugural address, said that he thought it would not be inappropriate for him to begin with a few remarks upon one or two departments of water engineering, in which knowledge had advanced or practice varied since 1878, when the famous water-engineer, Mr. J. F. Bateman, occupied the presidential chair. The most valuable and practical gain had undoubtedly been our enlarged insight into the very important work done by the ordinary sand filter, which at that time was not expected to do more than remove from the water such suspended matter as was visible to the naked eye. Since then germs, whether known simply as micro-organisms or as bacilli, bacteria, &c., had come very much into evidence, and had to be taken account of as potent agents for good or evil. The specially interesting thing about them to the water-works engineer was that, notwithstanding their minuteness they were almost entirely removed from water in the ordinary working of a sand filter. The signal service rendered by chemical methods in detecting sewage contamination might be said without exaggeration to be conspicuously reflected in the diminished mortality from typhoid and cholera in this country. There were many waters contaminated to a very slight extent only, and the question forced itself upon practical men whether these must be wholly avoided, or whether they could be rendered fit for domestic purposes by some simple process of purification, such as storage in large reservoirs or filtration through fine sand. But the changes effected by sand filtration being from a chemical point of view quite insignificant, the nature of the services rendered by this method of treatment remained obscure until an entirely new interpretation was placed upon them by the now well-known bacteriological methods of water examination. The importance attached to such examination was based on the suspicion that most natural waters might at any time contain bacteria capable of producing disease, and, although the majority were innocuous, a guarantee was required that no harmful ones should reach the consumer. This in the present state of knowledge could be secured only by the removal of all bacteria irrespective of their harmful or harmless nature, and therefore the value of a process was estimated according to the efficiency with which it did this. Whether it was right to do so was a question upon which he was bound to say he had always had a slight misgiving. We were still groping in the dark as to the work these ubiquitous micro-organisms were designed to do in the economy of nature. Might it not be wiser to assume the majority of them to be actively beneficent instead of being simply harmless? But this pessimistic view need not trouble us much, for health statistics proved that the risk of harm arising either from the presence in the water of so-called pathogenic organisms or from the removal of the harmless ones was so small that it might be calmly disregarded.

After some observations on use of stone dams for the construction of impounding reservoirs, Mr. Mansergh remarked that the hydraulic engineer probably represented the most ancient branch of engineering practice. This led him to enumerate some important hydraulic works of ancient times, beginning with a dam built across the Nile at Kosheish when Mena desired to build Memphis nearly 5,800 years ago. He proceeded to give a somewhat detailed account of the various aqueducts by which ancient Rome was supplied with water, drawing for his facts on the work of Sextus Julius Frontinus, who was appointed water commissioner of the city early in the second half of the first century of the Christian era. As to the amount of the supply in Frontinus's time, Mr. Mansergh said he had always thought there must be some exaggeration about the figure of 312 million gallons a day sometimes stated, and he agreed with the conclusion that a more likely quantity to be carried by the nine aqueducts in existence early in this era was 70 million gallons a day, 25 millions being lost or utilised *en route*, and 45 millions delivered into the city. But, as all the aqueducts were seldom in working order at one time, it would be right to make a still further deduction and reduce the quantity to 32 millions, equivalent to 32 gallons per head per day, assuming the population to have been one million. This might not seem a very large quantity, considering the volumes employed for baths and fountains, but, on the other hand, for purely domestic purposes the greater part of the people used only such water as was carried to their homes in jars. Many local sources were also available.

Mr. Mansergh next commented on the law of underground water, and, finally, discussing the water supply of fifteen important cities in the United Kingdom, Europe, America, and Australia, he called attention to the fact that, with a partial exception in Rome, all but one had their supplies administered by the public authority as directly representing the ratepayers and consumers; and he expressed the opinion that the fourteen were right, while the one (London), whose supply was managed by the directors of private companies, was wrong.

Correspondence.

The Origin of the Term "Galilee."

To the Editor of THE BUILDERS' JOURNAL.

SIR,—I have been reading quite a small collection of learned derivations of this word, It is surprising that the equally learned authors of these derivations should wander hither and thither through the Hebrew dictionary in their search, rather than, aided by the merest knowledge of philology, look at home.

One of the first things we learn in philology, if we have not already discovered it for ourselves by experience or observation, is that people will insist on pronouncing words in the easiest way—or the way easiest or nearest to themselves individually. Servant girls excel in this, and no doubt it is to them that we owe the term "banister," which probably now is quite classical and appropriated to the stair balusters. It is individuals such as these that find gall*e*y a much easier word than

gallery, and I have often heard the fast disappearing galleries of churches spoken of as "the gallelies" by members of this useful though despised and ridiculed class. Gallely (not Galilee) must, therefore, have nothing to do with the land of Palestine or the language of the Hebrews, but be merely a corruption of the word "gallery" or "galery" from the Low Latin *galeria*, a long porch (*porticus*). The ecclesiastical language has always been Latin, and, therefore, if "gallery" in the mouth of a servant-girl did not become "gallely" and so indicate the derivation, we ought first to go to the Latin before rushing off to Hebrew. As *galeria* is a long *porticus*, so most of the so-called "galilees" are large if not long porches; but whereas porches usually face north or south, "galelies" or "gallelies," on the other hand, are porches that face west, either at the west end of the church, as at Durham, Ely, Peterborough, Fountains, or in some other position (but still facing west), as that at Lincoln on the west side of the south transept; or else there is a division internally at the west end of a church, as at Leominster Priory, where a step called the "Galilee (galely) step" runs across the first or western-most bay of the north aisle and nave.

Yours truly,
BANISTER.

Low Side Windows.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—Pray allow me space for a reply to Mr. J. Russell Larkby's criticisms, on page 262 of your issue for October 31st, of my low side window theory. It is, as he says, a "vexed question," and without hoping to convert him to my view, I wish to remove any misunderstanding that may have arisen from some of the statements in my previous letter.

1. I did *not* quote Bedyll's letter as referring "*exclusively* to monastic establishments": indeed, my intention was to show that his remark as to the blocking up of openings in walls used as outward confessionals by the friar-confessors related primarily to such apertures in the outside walls of our parish churches and dependent chapels. The context of Bedyll's letter shows, I think, that this reference to the friars and their peculiar mode of hearing confessions is in the nature of an interjection, not strictly relevant to the subject on which he is writing—namely, the reluctance of the nuns of Sion and their spiritual advisers to accept the new title of Henry the Eighth as Supreme Head of the Church of England.

2. Apart from any particular theory of the dozen or more that have been advanced to account for these peculiar openings, it is a fact beyond dispute that they are rare in certain districts and non-existent in others, while, on the other hand, they abound in perhaps the majority of our English counties. This alone points to an irregular use, unknown or barely tolerated in some dioceses, sanctioned and encouraged in others. If the ringing of a sanctus bell were the object for which this class of windows was brought into being, such would not be the case; and, which further disposes of that explanation, it is well known that a sanctus bell-cot and low side window often exist side by side in the same church; or, which is the same thing in effect, a central tower and the window adjoining it in the chancel.

Mr. Larkby is quite correct in saying that low side windows are (for some reason I cannot explain) the exception in Kentish churches. Some time ago I published in "The Antiquary"* a list of examples known to me in that county, and they numbered only twenty-two. Since then I have met with one or two more; but undoubtedly the proportion to the number of churches is very much smaller than in such counties as Surrey, Sussex, Hampshire, Lincoln, or Northants. And in the churches of Kent, near London, as Mr. Larkby remarks, very few are to be found. Eynsford and Hartley—where two exist (one retaining its original shutter)—Meopham, Chalk, and Frindsbury are exceptions that Mr. Larkby may be glad to know of.

3. I have all along contended that the unequal distribution of these windows corresponds to the influence of the friars, which would be greater in one locality than in another; but I do not suppose that the friars *only* used these openings. I can even imagine that they came to be used when made, or were even in exceptional cases expressly built, for some other purpose altogether—e.g., the display of relics to a string of pilgrims (as must have been the object of two low side windows in the east wall of the chancel at Faversham, Kent); so many handy uses could be suggested when once such openings were in existence for the primary purpose of confession. That they are infrequent in the town churches—though I could quote many examples, nevertheless—only points to the fact that the friars found other more convenient means in the great centres of population of getting at the people. Their practice, as is well known, unlike that of the monastic orders proper, was to build their churches in a town or its suburbs, and to spread themselves abroad through the adjacent country, commonly journeying in couples. Mr. Larkby says that two low side windows in one church are comparatively uncommon. I cannot quite agree to this. Taking Sussex, for example, out of about seventy cases of churches with a low side window, at least twenty-one have two; one, if I am not mistaken, has three.

Mr. Larkby quite mistakes my meaning if he supposes that I intended to draw an analogy between the manners and customs of the anchorites and those of the friars. Everyone knows, of course, that they had very different ideals as to the religious life; that of the one being seclusion from the world, and that of the other missionary work of the most active and popular character. But the fact on which I insist is that both classes of "religions" were in the habit of attracting certain of the laity to resort to them for the purpose of making confession; and in the case of the anchorite, immured for life in a narrow cell, he could have heard these confessions in no other way than by means of the narrow barred and shuttered external aperture, which served him for light and air, the passage of food, &c. Here then is a low side window in all its characteristics, saving only that it is in a cell attached to the church, instead of in the wall of the church itself; and confession, beyond all question, was made at such openings in such cells. Is there anything so very unreasonable in supposing that the low side window of the church itself was put to a similar use? The thickness of the walls, *pace* Mr. Larkby, would be no difficulty, and the sills, where not actually niched-out, as at Warlingham, Doddington, Kent, and elsewhere, were commonly made flat on the inside to allow a person to sit on them. But of course it was never intended that priest and penitent should come to too close quarters.

Yours truly,
PHILIP M. JOHNSTON.

* For March, 1900.

Guide-Books.

To the Editor of THE BUILDERS' JOURNAL.

LONDON, N.W.

SIR,—As a genuine guide-book writer may I be allowed to add somewhat to the article on "The Average Guide-book," which appeared in your issue for last week. There are two sides to every question, and I wish to put the case of the not always fortunate compiler of local guides. Undoubtedly there are many guide-books (and not always cheap ones) which are written without local knowledge; but unless they have some very special recommendation they rarely survive the first edition. Guide-book architecture is often a wonderful thing; but are not architects themselves sometimes to blame for the extraordinary muddling up of styles? While one of our guides was actually in the press I received information that an important addition was being made to a building of some historical interest which I had described. I wrote to the architect and received the information that the building was in the Early English style. After the book was published and I was able to visit the completed erection I was disgusted to find that it was built in the Tudor style. Again, what is one to do when expected to describe one of those marvellous structures which consist of all styles mixed gloriously together but to write it simply "Gothic" or "Classic"?

It often happens that an individual having local knowledge cannot properly express himself in writing; and when trying to make his knowledge available and readable for other people, such a person is almost bound to copy and perpetuate similes which should have been decently smothered and buried long ago. Often local writers are unfitted to compile guides because the interesting places in their district have become too common to them to be properly appreciated. They rhapsodise over the new chimney-pot on Mr. Brown's house, and leave antiquities which have plenty of history attached to them without a word.

At the same time it must be admitted that one of the worst punishments that could be inflicted on some writers of guide-books would be to place them in a locality about which they had written with only a copy of their own misguiding guide to enlighten their way.

Yours truly,
B. C. DEXTER.
Editor, Millgate's "Kentish Guides."

Fletcher's "History of Architecture."

To the Editor of THE BUILDERS' JOURNAL.

BELFAST.

SIR,—I shall be glad if any of your readers can put me in the way of getting a copy of Banister Fletcher's "History of Architecture." I have tried Mr. Batsford and several other booksellers, but without success.—Yours truly,
PUPIL.

An Underground Architecture.

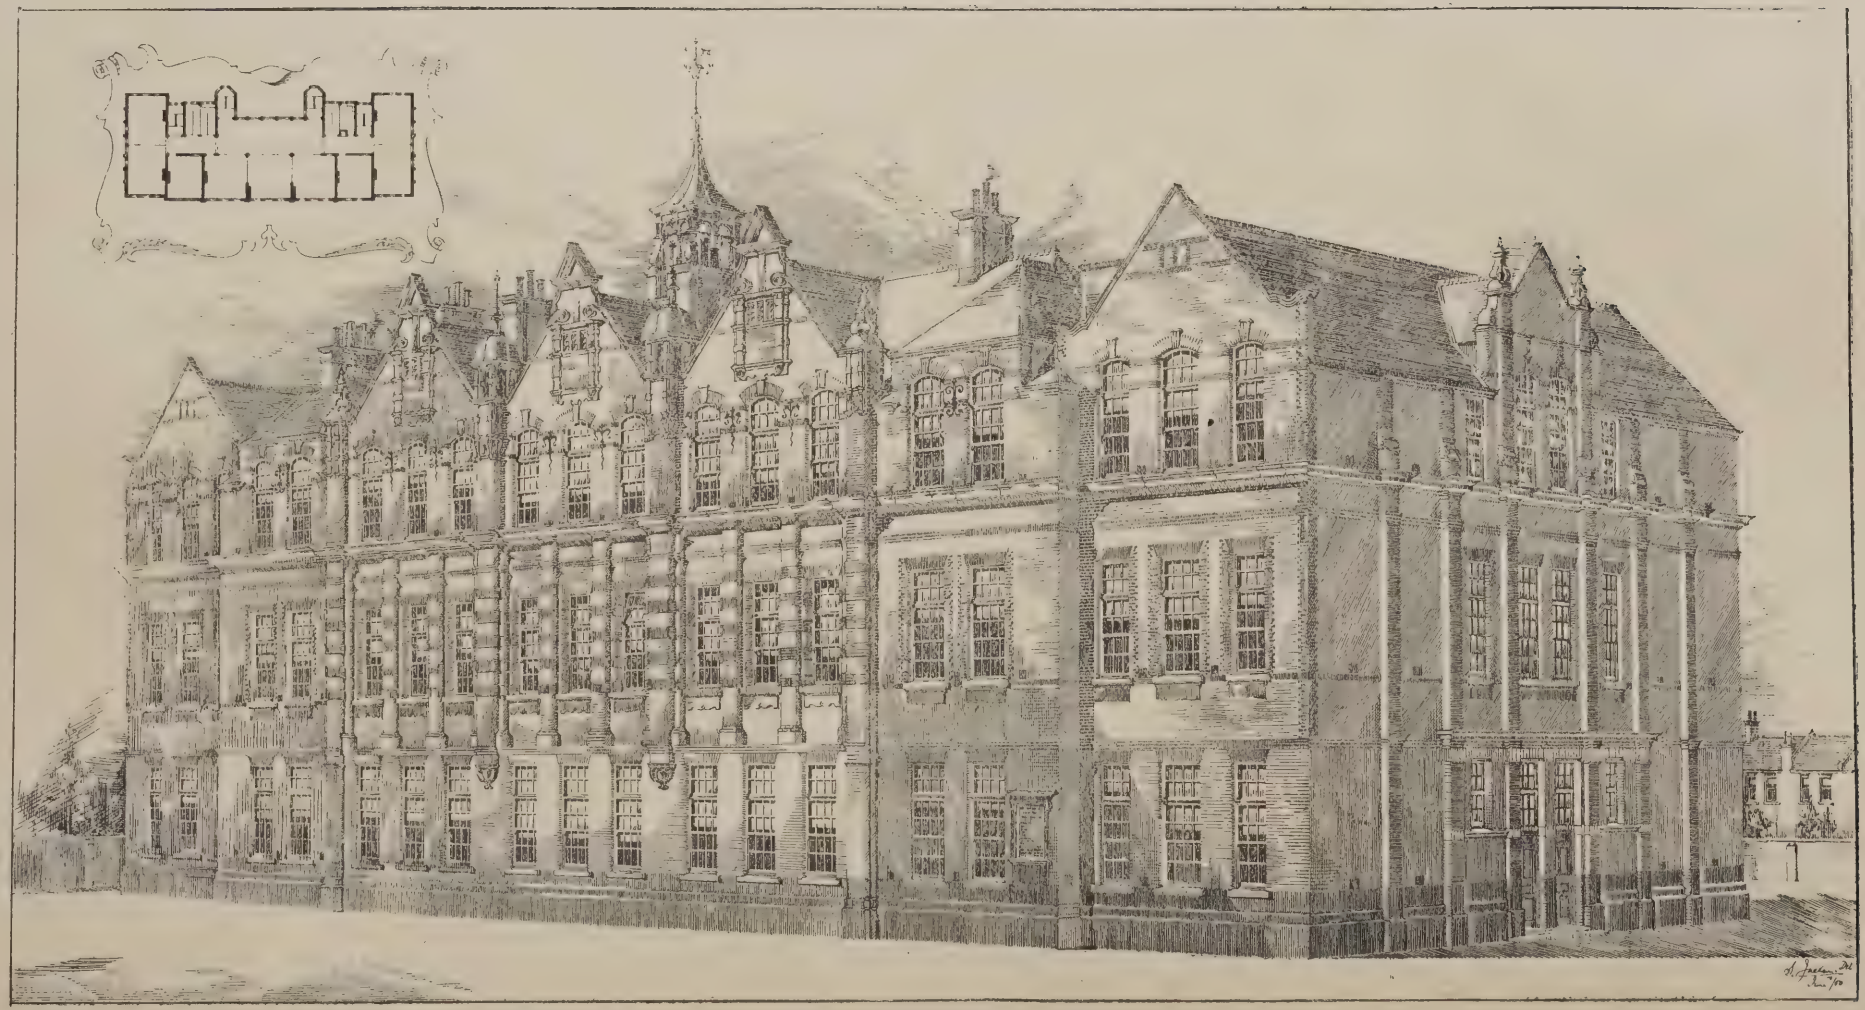
To the Editor of THE BUILDERS' JOURNAL.

LONDON, S.W.

SIR,—How does "G. W. H." propose to drain his buildings ten storeys below the ground?

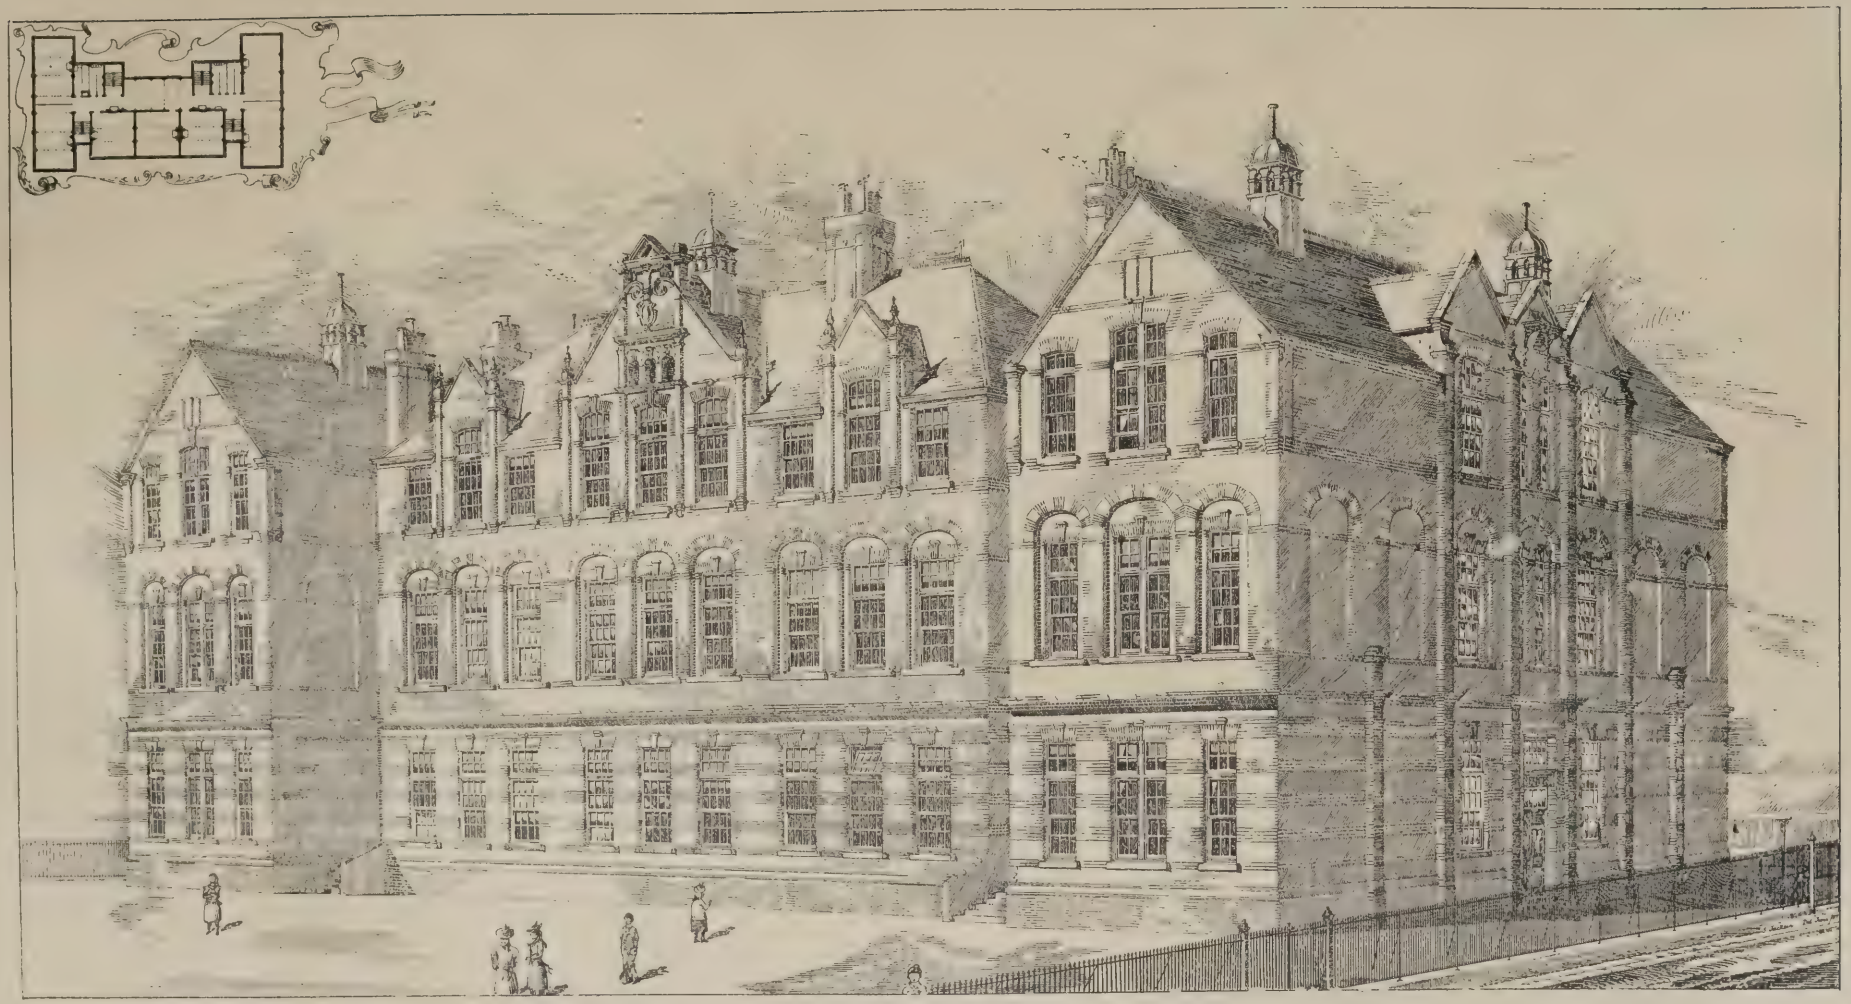
Yours truly,
M. J.

THE BUILDING TRADES' GIFT.



MR. T. F. RIDER, as honorary secretary to the Building Trades' Gift to the Nation, announces the following additional subscriptions which have come to hand:—

	£	s.	d.
The Building Trades of Walsall (per Mr. W. Wistance)	200	0	0
The Birmingham Master Builders' Association (per Mr. W. Sapcote, third instalment)	100	0	0
Messrs Holloway Brothers	52	10	0
The Nottingham Master Builders' Association (per Mr. W. J. Barton, second instalment)	47	5	0
Workmen of Messrs. Holloway Brothers	25	2	1
THE BUILDERS' JOURNAL Shilling Fund (second instalment)	14	17	9
The Employés of Mr. Walter Wallis (per Mr. A. Sweetman)	7	11	0
Mr. T. W. Heath and Workmen, Kensington	3	3	6
Workmen of Messrs. T. Rider and Son	3	0	0
Mr. A. S. Turner and Workmen	2	12	0
Messrs. G. Candler and Sons and Workmen, Brixton	1	18	9
Mr. C. Kibley and Workmen, Plumstead	1	17	0
Workmen of Messrs. Barnes and Co., Shoreditch (third contribution)	1	17	0
Mr. Burkitt (per Mr. Robert Neill)	1	1	0
The Yorkshire Federation of Building Trades Employers (per Mr. W. R. Thompson)	0	17	6
Messrs. H. Stevens and Co., Southampton	0	8	6
Messrs. M. and E. Whewell, Blackburn	0	6	0



The Glasgow Institute of Architects held an extraordinary general meeting on Tuesday, Mr. David Thomson in the chair. A special resolution was confirmed bringing the declaration required from members of the local institute into confirmity with the declaration of the Royal Institute of British Architects. At the same meeting reference was made to the death of Mr. Young, architect of the Glasgow Municipal Buildings and other important works, and the secretary was instructed to minute an expression of sincere regret thereon. At the close of the general meeting a meeting of the Alexander Thomson Memorial Trustees was held, under the presidency of Mr. T. L. Watson, for the purpose of examining the drawings and sketches submitted by Mr. D. Rome Guthrie, the Alexander Thomson travelling student. Descriptive notes of Mr. Guthrie's journey were read by Mr. M'Gibbon, and the trustees considered that the drawings and notes afforded highly-satisfactory evidence of his having made due improvement of his travels during at least three months.

Bricks and Mortar.

APHORISM FOR THE WEEK.

There is no genuine love for art without an ardent love for humanity.—F. HORN.

Our Plates. A CRITICISM of the Holborn-Strand designs appeared in our issue for October 31st. The Essex Road School was erected by the Little Ilford School Board, Essex, and was opened in August, 1898. Little Ilford is an ecclesiastical parish within the area of the district governed by the East Ham District Council. A scheme for the amalgamation of the Little Ilford School Board with its larger neighbour the East Ham School Board was promoted and took effect in March last. The school is built to accommodate 1,582 scholars—582 infants on ground floor, 500 girls on first floor, and 500 boys on second floor. The site comprises an acre and a half, and in the playgrounds latrines, caretaker's store, tank room, and caretaker's cottage are erected. The total cost of the buildings was £14,315. The Kensington Avenue School is now being erected by the Little Ilford School Board to accommodate 1,573 children—541 infants, 516 girls, and 516 boys. The corridors, cloak rooms, and mezzanine floors are fireproof throughout. The dadoes to the corridors are in salt-glazed bricks. A feature in the plan is that the three central classrooms and the central portion of the corridor, on each floor, can be converted into a large central hall, movable partitions being provided, as shown on the plan. The heating to all the classrooms and teachers' rooms is by means of open fireplaces, and in the corridors and cloak rooms by hot water. A caretaker's cottage is also being built in the playgrounds. The contract sum is £20,566. The architect for the two schools is Mr. S. Jackson, 65 Fenchurch Street, E.C., and the builders are Messrs. Gregar and Son, Jupp Road, Stratford, E.

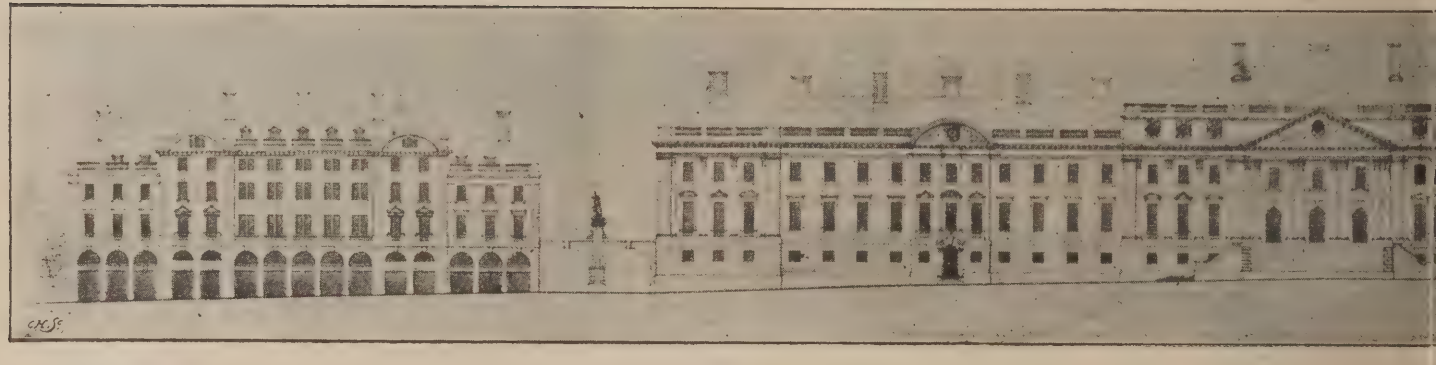
Holborn-Strand Designs. THE present position with regard to the designs submitted for the Holborn-Strand thoroughfare is that Mr. Norman Shaw and the Council's superintending architect have presented a joint report to the Improvements Committee, and they have singled out three designs as containing architectural features which commend themselves to their judgment. The Council's valuer has been instructed to prepare a report on the financial aspect of these three designs, and when that is ready the Committee will come to a decision. Officially, not one of the names of the architects of the eight designs which have been sent in is known yet, although very good guesses are being freely made on all sides. Even the authorship of the three designs recommended by the assessors has not yet been declared; the Committee only knows them by numbers. At last week's meeting of the Improvements Committee it was proposed that the sealed envelopes containing the architects' names should be opened, but after some discussion it was decided to keep the names sealed up until the Committee had come to a final decision.

HOLBORN TO STRAND THOROUGHFARE. PLAN OF DESIGN No. 23.

Egypt Exploration Fund. AT the fourteenth annual general meeting of the Egypt Exploration Fund held on Wednesday last at the Geological Museum, Jermyn Street, Sir John Evans (president) occupying the chair, the treasurer stated that the total assets of the exploration fund, the archæological survey, and the Græco-Roman branch amounted on July 31st last to £3,806. This sum was to be appropriated as follows: To the exploration fund, £2,180; archæological survey, £621; Græco-Roman branch, £1,004. The president then delivered his address, in which, after referring to the loss by death of several eminent supporters of the fund, he detailed some of the work effected by the fund, and some of the progress made in Egyptology. Research in Egypt appeared never to have been prosecuted with a greater degree of activity than it had been during the past season. The hon. secretary followed with his report, in which he pointed out that, though they were an English society, they were largely indebted to American support, nearly half of their aggregate income for the past year having come from the United States. At the conclusion of the secretary's statement Professor Petrie delivered an address. Step by step, he said, the past had been won back to them, and the mysterious ages, which no man ever hoped to know again, had been laid bare to them. Seven cycles of civilisation, a thousand years or more apart, had taken them back to the beginnings, with strides for which the two cycles in Europe, the classical and the mediæval, scarcely prepared them. Such was the wider aspect of human history which the work, solely of English exploration in Egypt, now put before them.

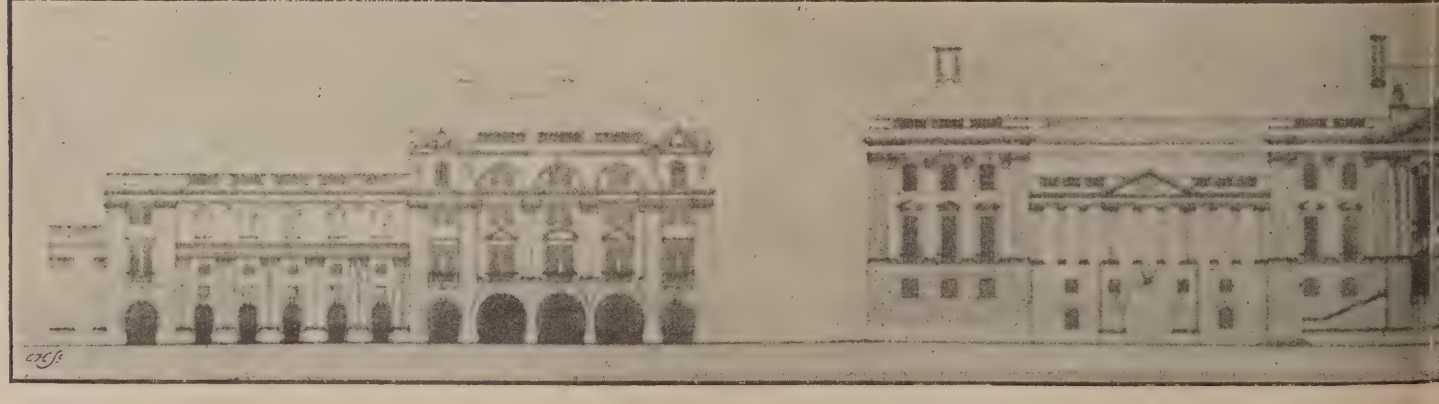
Marylebone Chapel. DURING last week the 500th anniversary of the foundation of what is probably the smallest church in London, though one of the most interesting—the Parish Chapel of St. Marylebone—was celebrated. It stands at the top of the High Street, unknown to many lovers of antiquity and unnoticed by the general public, but containing a fine collection of monuments to noteworthy persons. On an altar tomb to the family of Deschamps, near the vestry door on the south side of the churchyard, Hogarth has represented the "Idle Apprentice" playing marbles with his companions; while the interior of the older building, pulled down in 1740, is shown in Hogarth's picture of the "Marriage of the Rake" now at the Soane Museum in Lincoln's Inn Fields. The famous architect, James Gibbs was buried in this church. He designed the Radcliffe Library and the New Quadrangle of All Souls College, Oxford, the new building at King's College, Cambridge, the Senate House at Cambridge, the Duke of Newcastle's monument in Westminster Abbey, the Church of St. Martin-in-the-Fields, and other well-known buildings. He left £100 for the enlarging of the church, and is commemorated by an unpretending monument, on which the fact is stated. Not the least interesting living features connected with the church are the children of the Marylebone Charity School, in their picturesque, old-world costume, so well represented in Miss Florence Small's picture exhibited in the Royal Academy of 1894. Lord Byron and probably "little Dombey" were baptised in the chapel, and it is to be hoped that no injury will be done to it on account of the parish authorities refusing to maintain it any longer after having put it in thorough repair.

The White House. A FEW years ago an estimate was given of the cost up to date of the White House at Washington, when it was found to amount to about £466,400. This included furnishing, repairs, and improvements to the grounds. From Washington to Grant the salary was £5,000 a year, but in Grant's time it was doubled, being even then, relatively to the cost of living, less than Washington's. To-day the various allowances of all kinds, which are on a liberal scale, bring the value up to about £14,000 a year, and the President of the United States is richer at that than the President of the French Republic, as so very much less in the way of expense is expected from him.



An Old Sign. THE gilt half-moon which projected from a very old house in Holywell Street, so familiar to passers-by, has been removed to the home of the London County Council, where it is to form the nucleus of a museum of London antiquities. The house, though closed and doomed, still stands, immediately to the west of the covered way from the Strand now known as Half-Moon Passage, though at one time it bore a much less respectable designation. The eastern corner-post at the Holywell Street end of this passage used to be adorned with a curiously-carved lion's head and paws, which are now to be seen in the Guildhall Museum. It has been suggested by Mr. Norman, in his "London Signs and Inscriptions," that this may have had some connection with Lyon's Inn, with which a continuation of the passage on the other side of Holywell Street at one time communicated. Diprose, in "Some Account of the Parish of St. Clement Dane," tells us that the half-moon was once the sign of a tradesman who was staymaker to George the Third. It is thought by some that, as Holywell Street is but a little way outside the City boundary, and the Guildhall Museum already possesses a most interesting collection of old signs, the half-moon should be restored to the companionship of the Lion, its near neighbour for perhaps a couple of centuries. The lower horn of the moon was a modern restoration.

Hassan's Mosque at Cairo. THE famed mosque of Sultan Hassan at Cairo, dating from the latter part of the fourteenth century, is to be repaired, but the fact that Herz Bey is architect to the Committee for the Preservation of Monuments of Arabian art in Egypt may be taken as a guarantee that there will be no "restoration." A book on Sultan Hassan's mosque, written by Herz Bey, and published by the Committee, should be read by such visitors to Grand Cairo as feel interested in its monuments. The Committee to which he is architect was founded nearly twenty years ago. Since then, and largely through the influence of Lord Cromer, the people of Egypt, and of Cairo in particular, have manifested a regard, unknown in earlier times, for the preservation of their historic buildings. It is estimated that the repair of Sultan Hassan's mosque will cost £40,000 sterling.



County Architect for Lancashire. AT the last meeting of the Lancashire County Council, held at Preston, the recommendations of the Finance Committee were adopted. These included "that, in lieu of Mr. Henry Littler's present appointment as architect to the Standing Joint Committee, he be appointed county architect for all County Council and Standing Joint Committee purposes, including the supervision of all county buildings, at a nett salary of £1,200 (without pension), with all necessary staff and offices provided for him; and that such appointment be made subject to the following terms and conditions, that is to say:—1. That the salary commence as from March 31st, 1900, in lieu of all fees in connection with the extension or alteration of the county offices. 2. That the balance of his fees agreed to be paid him for the Preston Sessions House be paid on completion of the buildings. 3. That he be not allowed to take any private practice, but may act for the Lancashire Inebriates Acts Board if asked to do so. 4. That the appointment be determinable by either side on giving three months' notice. 5. That £1,000 per annum of the total cost of the county architect's department be charged to the general police account." The question of such an appointment arose about five years ago, and as there were three departments in the county administration in which the employment of an architect was necessary—the Asylums Board, the Finance Committee, and the Standing Joint Committee—those bodies took up the question. At that time the Asylums Board declined to favour the appointment; the Standing Joint Committee desired it, while the Finance Committee withheld their approval on account of the action of the Asylums Board. Mr. Littler was appointed as architect to the Standing Joint Committee alone at a salary of £600. It is thought that his new appointment will prove a financial advantage to the Council.

OF CURVED STREET.

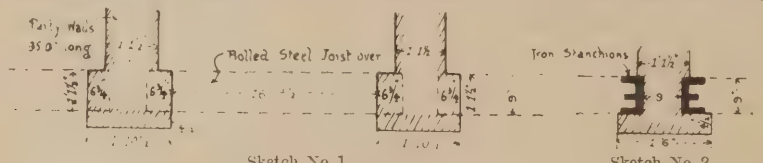
STRAND.

OUGHFARE. Design No. 23.



Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Supporting Ends of Girder.

X.Y.Z. writes: "Sketch No. 1 shows an opening over which a wall, floors, &c., have to be carried on steel joists 4½in. back from the face of the piers. Local by-laws will not allow the ends of joists to approach nearer than 4½in. to centre of party wall, which permits a bearing of 6¾in. only. The weight transmitted by the end of each joist is 9 tons, total 18 tons on each pier. Would a brick pier of size shown be sufficient to carry this weight, or would iron stanchions have to be built in, as shown by sketch No. 2? The brick pier cannot be larger than shown. Spons' engineers' tables give 5 tons per ft. super. as the safe weight for brick piers. The area of the pier in sketch is 1·91 × 1·12 = 2·1392ft., and would therefore only carry 10·6960 tons; but would not the adjoining party wall assist the pier? I find steel joists 10in. × 4½in. will carry 9·25 tons each. Is it enough to lay them side by side, or should they be joined; and, if so, would bolting through the web with distance pieces be sufficient?"

Rolled joists side by side are commonly bolted together by distance pieces every 3ft. or 4ft. The holes being in the centre of the web do not reduce the strength appreciably. The safe

Sketch No. 1. Sketch No. 2.

SUPPORTING ENDS OF GIRDER.

load upon brickwork, with a 4in. York stone template of full area interposed, is:—

	Tons per sq. ft.	
Blue brick in cement ..	9	= ½ of fracture load.
Stock brick in cement ..	6	= ⅓ "
Stock brick lias mortar ..	5	= ¼ "
Stock brick in grey lime mortar	4	= ⅓ "

with a maximum for dead loads of 50 per cent. more than above, and a reduction when height of pier exceeds six times its least thickness, namely, w = tons per ft. sup. as given above, r = ratio of height to least thickness; safe load tons per sq. ft. $= \frac{24\,w - wr}{18}$. In the present case the pier being securely bonded into party wall may be considered capable of bearing the full load. 1ft. 10½in. = 1·875, 1ft. 1½in. = 1·125. 1·875 × 1·125 = 2·1 sq. ft. Stock bricks and grey lime mortar, dead load 6 tons per ft. 2·1 × 6 = 12·6 tons total load on whole pier, which is therefore insufficient to carry 18 tons. If the pier were built from footings upwards of stock bricks in cement it would be just strong enough, but there would be no margin to allow for contingencies. HENRY ADAMS.

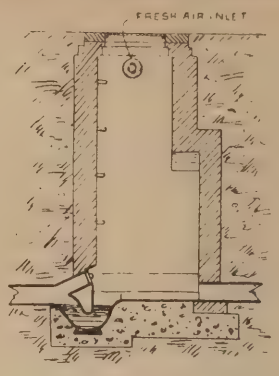
Corrosion of Iron when Built In.

BIRMINGHAM.—LE SOUPÇON writes: "I have always considered it a mistake to make use of hoop-iron (either galvanised or coated with tar or paint) in brick walls as an agent for strengthening or bonding them, particularly in outer walls. The objection to its use has often been noticed in taking down old buildings where it has been used; there has invariably been more or less of a fracture by reason of corrosion and consequent expansion all along the course where the iron was inserted, with the result that the wall was considerably weakened. Am I right in this? Further, while R.S. joists are very extensively used (and with great success) in the construction of suspended concrete flooring, I hold that it is not wise to use iron in large concrete blocks such as engine beds for large and powerful engines running at high speeds, and where it is absolutely necessary to prevent vibration. Therefore in a block of 4 to 1 concrete 24ft. square on plan and 13ft. deep, is it wise to use 5in. cast-iron pipes in which to insert the engine foundation bolts, afterwards to be grouted in cement, the bolts and pipes to be built into concrete 11ft. deep? The pipes are not galvanised or covered with any kind of paint. Will corrosion occur and cause fracture of concrete?"

If the hoop iron is new when built in and not rusty before it is painted, tarred, or galvanised, and the wall is built of sound hard bricks with proper damp-proof course, there ought to be no danger of serious corrosion. If our correspondent has "often noticed" the contrary he ought to have looked for the special cause. Iron cannot rust without access of air and moisture; therefore, in dry foundations iron embedded in cement-concrete is practically everlasting. The high steel-frame buildings in New York, twenty or thirty storeys in height, are resting upon such foundations. For foundation bolts in engine beds the writer's practice has been to use a square hollow box of wood, about 3in. × 3in. × 3ft. long, made out of 1in. stuff, and to draw it upwards from time to time as the concrete is deposited. Afterwards, when the bolts are inserted, leaving them alone or grouting in. The cast-iron pipe may be used if preferred and left in without any fear of bursting the concrete. In an account of the Broadway Chambers, a modern office building in New York, 235ft. high, the architect of it, Mr. Croydon T. Purdy, says: "The direct contact of Portland cement in the form of grouting seems to be one of the surest methods of preventing corrosion." Again, he says: "For exterior walls nothing has been found to so perfectly protect the steel embedded in them as first-class hard burned brick, laid in cement mortar, and this is also the best protection against corrosion." HENRY ADAMS.

Counterbalance of Cantilever.

BRIGHTON.—Assoc. San. Inst. writes: "With reference to 'G.A.T.M.'s' answer on page 229 of your issue for October 24th, is there not an error in taking moments about the fulcrum $16\frac{2}{3} \times \frac{y}{2} = 5 \times 5$ and not $33\frac{1}{3} \times \frac{y}{2} = 5 \times 5$, which is equal to 'G.A.T.M's' method $A = \frac{2 \times 5, \times 5}{1\frac{1}{2}}$ where A = Z? Mr. Middleton has calculated the load A as distributed and acting at the centre of wall $\frac{y}{2} \times A = \frac{2 \times 5 \times 5}{3} = 16\frac{2}{3}$ tons is identical with $Z \times \frac{y}{2} = W \times l$ where A = Z."



The thickness of the wall should have been stated as 18in., or 1½ft. Our correspondent has evidently assumed it to be 3ft. thick, when the calculations would be right.

G.A.T.M.

Ventilating Drains.

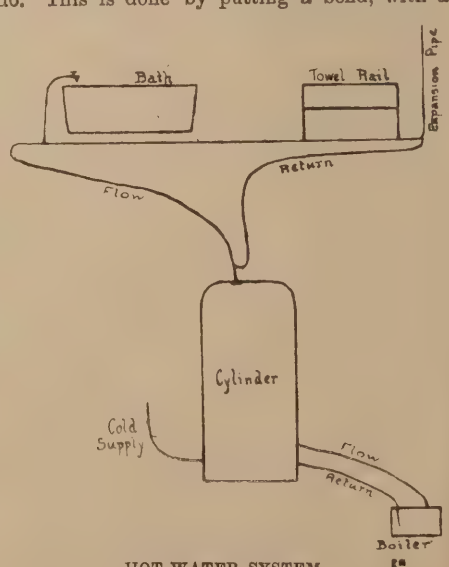
LLANGOLLEN.—SANITAS writes: "Kindly state the best method of ventilating the drains of a house situated about 90ft. above the town, and connected with the main sewer."

The ordinary method of constructing a disconnecting chamber for stoneware drains is shown in the accompanying sketch, the fresh-air inlet being placed near the *top* of the manhole. By this arrangement any accumulation of sewer air within the upper part of the chamber is prevented. If the bottom of the manhole has been constructed with an intercepting trap and a *whole* split pipe (i.e. a pipe properly prepared for splitting, but still intact),

VENTILATING DRAINS.

as indicated in our correspondent's sketch (not reproduced), it is recommended that the fresh-air inlet be directly connected to the trap inlet marked R (on correspondent's sketch). The fresh air will then have direct connection with the house drains, the sewage passing through the chamber in closed pipes instead of the usual open channels. T. E. C.

Books and Articles on Perspective Drawing.



PRESTON.—NOUVEAU writes: "Which are the best books published on architectural perspective dealing with the subject in an elementary manner, and showing the quickest methods of obtaining the necessary vanishing points, heights, &c., sufficient for making perspective sketches of villas, business premises, &c.? Have a series of articles appeared in your journal on this subject?"

"Linear Perspective," by G. A. T. Middleton, A.R.I.B.A., 1s.; "Architectural Perspective," by F. O. Ferguson (2nd edition), post free, 3s. 3d. These books can be obtained from B. T. Batsford, 94 High Holborn, W.C. An article on "Perspective in Everyday Practice," by W. N. Cumming, appeared in the BUILDERS' JOURNAL for the following dates:—October 28th, 1896; November 4th, 1896; December 9th, 1896; March 3rd, 1897; March 17th, 1897.

Details of Hot-water Supply Apparatus.

WOLVERHAMPTON.—P.M.T. writes: "Which is the best method to adopt in connecting the pipes for a bath for hot water upon the cylinder principle, allowing a return pipe for the purpose of heating a towel rail? Do you think the principle shown in the accompanying sketch is a good one? I shall be glad to know which text-book on hot-water heating you would recommend."

The sketch shows an apparatus on the cylinder system, in a simple form, but lacking some details essential for efficacy. The flow-pipe from boiler enters cylinder about 8in. from the bottom and does not appear to extend up inside a little more than half-way, as it should do. This is done by putting a bend, with a

HOT-WATER SYSTEM.

iece of pipe in it, on to the flow connection nside the cylinder; or, the same result can be btained by connecting the flow-pipe at a igher point outside. This pipe must terminate n or at the cylinder $\frac{5}{8}$th of the way up from ottom to top. Another omission is the empty- ng cock or branch which must be put some- here below the cylinder. The cock should ave a loose key (to be taken away) so that it nay not be used by the servants. The sketch hows the secondary flow-pipe extending from he top of the cylinder, circulating past the ath to a towel-airer. This is a satisfactory rrangement, but the secondary circulation has s return connected wrongly. The return is hown connected to the flow, so that although here is a circuit there is only one connec- ion to the cylinder. This will not work. he secondary return must enter the side f the cylinder 4in. from the top, or it an come through the top and project down nside 4in. It must not terminate lower. as sizes of boiler, cylinder and parts are not iven, no opinion can be expressed regarding hese. The only text-book dealing fully with he two subjects of heating by hot water and omestic hot-water supply is "Hood on Warm- ng Buildings," published by E. and F. N. Spon, imited, 125 Strand, London, W.C. F. D.

Tracing Cloth.

CHORLTON-CUM-HARDY, MANCHESTER.—. B. writes: "Which is the proper working ide of tracing cloth, the glazed or the dull ide?"

The glazed side of tracing cloth is that most ommonly drawn upon, the surface being first ubbed with chalk or with india-rubber. When halk is used there is a chance of the pen icking up some which may have been left on he cloth and thus causing an imperfect line to e drawn. On the other hand, while there is o necessity to use chalk when making a rawing on the reverse side of tracing cloth, he lines cannot be so easily removed as on the lazed side, should a mistake be made.

ooks on Vaulting and French Renaissance Architecture.

ILKLEY.—R. F. writes: "Please name a book n vaulting which gives complete working draw- ngs showing the whole process of projection, c., with a full and clearly-written description f how the drawing is set out. I should also ke to know of one or two good works on rench Renaissance architecture."

The best book on vaulting is Professor Willis' aper read before the Royal Institute of British rchitects, and published in their "Transac- ons" for 1842, a copy of which can be btained from Mr. B. T. Batsford, 94 High olborn, for 5s. nett. "Rational Building," eing a translation of the article "Construc- ion" in the "Dictionaire Raisonné de l'Archi- ecture" of M. Viollet-le-Duc, will also be use- ul. The cost is 12s. 6d. nett. Nearly all books n French Renaissance are large monumental ooks of plates; such as Sauvageot's "Palais, hateaux, Hotels, &c.," four volumes, folio, with ngraved plates, price £10 10s. nett; Berty's La Renaissance Monumental en France," two olumes, price £3 10s. nett.

Builders' Levels.

FROME.—Z. S. C. writes: "Can you kindly dvise where to get a builder's level, as low in rice as is consistent with a thoroughly reliable nstrument?"

Apply to Mr. Clarkson, 28 Bartlett's Build- ngs, Holborn Circus, E.C.; Mr. W. F. Stanley, and 5 Great Turnstile, Holborn, W.C.; or lessrs. T. Cook and Sons, 8 Victoria Street, .W.

Books on Practical Masonry.

SOUTH WIGSTON, LEICESTER.—R. M. writes: Who is the publisher of Purchase's book on Practical Masonry'?"

"Practical Masonry," by W. R. Purchase price 6s. 3d. post free), is published by Mr. . T. Batsford, of 94 High Holborn, W.C.

EXCAVATIONS AT CAERWENT.

DISCOVERY OF ROMAN HOUSES.

CONSIDERABLE interest is still being taken in the excavations at Caerwent, near Newport, Mon., and at the recent meeting of the Caerwent Exploration Fund, held under the presidency of Lord Tredegar, a report on the work done was submitted by Mr. A. E. Martin, F.S.A., the hon. secretary. The subscribers passed a resolution expressing their sense of the loss they had sustained by the death of the Marquis of Bute, who had been a valued supporter of the fund, and whose loss to archæology in general, said Lord Tredegar, would be very great.

The site of the excavations is a piece of ground about three acres in extent, and forming part of a larger field which it is hoped, if funds permit, to excavate completely in the course of the next two years. Indications are not wanting that the whole field contains buildings of considerable interest and importance. Upon the extreme east edge of the plot of ground which is at present under examination two of the brick pillars which supported the floor of a hypocaust have been found, and they are so well preserved as to suggest that if it is possible to continue the explorations of this interesting building discoveries of great importance may result.

The houses which have so far been discovered are remarkable for the solidity of their construction and the strength of their stone walls. In one place the foundations had been sunk to a depth of 12ft. in order to obtain the requisite degree of strength. Masonry so good is not frequently found in England, except in the camps of the wall of Hadrian, which crosses England from the mouth of the Tyne to the Solway. It is, for instance, incomparably superior to the work which is seen in the walls of the houses at Silchester, though that was a far richer and larger city. The city walls, too, are remarkably fine. The line of them is traceable on all four sides, especially on the west and south. On the south side they are in excellent preservation, portions of them still standing 20ft. high on the outside. On the inside they are not visible to so great a height—that is, they do not stand entirely free, but are to a certain extent embanking walls, as is clear from the existence of two lines of weepholes, one above the other, at certain points. Three bastions were added at a later date to the south wall, in the portion between the south gate and the south-west corner, probably with the object of strengthening the wall, which shows signs of having been extensively repaired.

The mention of the walls raises the problem as to the origin of Caerwent. Without going into the matter deeply (those who wish to do so may be referred to Mr. A. T. Martin's paper in the proceedings of the Clifton Antiquarian Club for 1894), it may be stated shortly that it is probable that Caerwent was originally a Roman camp, marking a stage in the Roman advance into South Wales posterior to the occupation of Gloucester, and anterior to the foundation of the legionary camp at Caerleon. An invariable maxim of the Romans was to secure newly-conquered territory by the construction of a military road, protected by fortified posts; and thus it is that the Roman road from Gloucester which secured the conquered territory of the Silures, which is still the high road into South Wales from the east, passed through the centre of Caerwent (Venta Silurum) and went on to cross the Usk at Caerleon (Isca Silurum). But at the time from which the buildings now under investigation date, it is probable that Caerwent had almost entirely lost its military character, and had become nothing more than a small country town. Owing to the inclemency of an English winter it is impossible to leave the buildings open without adequate protection, and this would be extremely costly. It will therefore be necessary to restore to cultivation the plot which has been examined this year, and to deal with another at the commencement of next season, if funds permit this to be done. The unique interest of the site, and the importance of the discoveries already made, and still more of those which may be expected as the centre of the city is reached, should surely serve to arouse such a degree of archæological enthusiasm in the neighbourhood as will ensure a continual influx of subscriptions. The honorary treasurer is Mr. A. E. Hudd, 94 Pembroke Road, Clifton.

Builders' Notes.

Mr. John Cross, a well-known builder, of Hutton, died recently at the age of seventy-five years.

Welsh Slates for the Transvaal.—The first consignment of slates for the Transvaal took place the other week. They were shipped at Portmadoc. Several other consignments are to follow. Trade is, however, very slack.

Leeds Corporation Candidates.—The Leeds Building Trades Federation requested the whole of the candidates for the Corporation to send answers to the following questions:—1. Are you in favour of all building materials removed from insanitary areas being destroyed. That no part of any such shall be employed again in the erection of dwelling houses. Will you assist in stopping such practices? 2. Are you in favour of the Corporation adopting and carrying out the provisions and amendments made from time to time in the Housing of the Working Classes Acts, 1890 to 1900. Will you vote for the same? 3. Are you in favour of an all-round system of workmen's trams, the property of the Corporation, of half-fare for the ordinary stages, that is, full fare for one return journey per day. Will you vote for the same? 4. Are you in favour of a Fair Contracts Committee being formed from the various committees, who shall be the authority to investigate breaches of the fair contracts clauses, who shall hear the employer and employees' case together as a committee?

London County Council.—At last week's meeting of the Council the report of the Improvements Committee in relation to the widening of London Wall and Blomfield Street was discussed. In the first part of the report the Committee recommended the Council to adhere to its decision to refuse to contribute towards the widening of London Wall between Albion Place and Circus Place. The second part of the report recommended that the estimate of £5,000 submitted by the Finance Committee should be approved, and that the Council agree to contribute one-half of the nett cost of the widening of Blomfield Street and London Wall between Finsbury House and Circus Place, proposed to be undertaken by the City Corporation, such contribution not to exceed the sum of £5,000. The Improvement Committee also recommended that the estimate of £51,443 submitted by the Finance Committee be approved, and that the Council accept the offer to sell for £50,000 the fee-simple in possession of their property fronting the western side of Millbank Street and the northern side of Church Street, having an area of about 12,500 sq. ft., and needed for the widening of Millbank Street, the trustees also arranging with the lessee for cancelling the building agreement. The Improvements Committee also recommended that, subject to the local authority consenting to the proposed tramway from High Road, Tooting, to the county boundary at Waterfall Bridge and agreeing to contribute one-third of the cost of the necessary street widenings, the Council should apply to Parliament for powers to widen Merton Road, the total nett cost of which is estimated at £28,000. The three foregoing recommendations were adopted after discussion. In reply to a question, the chairman of the Parks Committee said that a letter had been received from Mr. Henry Burt declining to accept the contribution of £7,000 by the Council towards the purchase of the Alexandra Palace, on the ground that the conditions imposed by the Council could not be accepted. The chairman of the Fire Brigade Committee, replying to a question, said the Committee were considering the question of adopting motors for their fire-engines.

Keystones.

A New Board School at Hendon is being erected at a cost of £20,245.

A Stained-Glass Window at St. Just-in-Roseland Church has been erected.

A new Customs House at Southampton is to be erected at the new entrance to the docks by the platform.

"Some Scottish Homes" was the title of a paper read by Mr. W. J. Blain before the Glasgow Architectural Association last Wednesday week. The paper was published with illustrations in our issues for February 17th and 24th, 1897.

A Proposed Clock Tower in Torquay.—As a memorial to the late Mr. Mallock, for many years member of Parliament for the Torquay Division, it is intended to place a clock tower in Torquay and a brass in the interesting old parish church of Cockington.

St. Ethelburga's Church, Lyminge, Kent, one of the oldest churches in England, has just been reopened after being placed in much-needed repair. The fabric had suffered severely from old age and inclement weather, and the renovation was undertaken to save it from further decay.

A new Police Station at Highgate is being erected. The site cost £1,300, and adjoins the new police court in Archway Road. A site has been purchased for a new station at East Finchley, and the one in course of erection on the site of the old Grecian Theatre, City Road, is approaching completion.

A New Refuse Destructor at Lambeth has been erected by the Strand District Board on the foreshore, opposite Somerset House, at a cost of £10,241. The destructor is of the Horsfall type, and comprises six separate furnaces. It will consume about 80 tons of refuse per day at an estimated expenditure of £2,562.

Major-General Baden-Powell and a Cardiff Builder.—Mr. John Garbett, of Crynant, who is building a new terrace in the town, the foundation-stones of which were laid on Mafeking Day, determined to name it Baden-Powell Terrace, and, having written to the gallant officer, received a reply from Pretoria saying he felt proud and highly honoured, and hoped it might have a bright and prosperous future.

The Interior of the London Pavilion has been practically rebuilt. The decorations of the music-hall are in cream and gold, relieved by terra-cotta draperies, whilst the panels are filled with allegorical pictures in Louis XV. style. This is the work of Mr. J. M. Boekbinder. The stage has been lowered 4ft., and there is an uninterrupted view from all parts of the house. The seating accommodation has been considerably increased, and a saloon placed underneath the stalls.

The Church Crafts League, which was inaugurated in February last by a number of influential clergymen and artists, under the presidency of the Bishop of Rochester, announces its first annual general meeting for the evening of Tuesday, November 20th. The meeting will be held at Bishop's House, Kennington Park, and will commence at 8 p.m. A limited number of tickets will be available for the use of non-members, and the secretary requests that early application for these be made to him at the Church House, Westminster, S.W.

Truro Cathedral to be Completed.—The Executive Committee of Truro Cathedal Building Fund have received sufficient money to justify them in giving the order for the full contract which will complete the nave and west front, and western towers to the eaves of the nave roof, thereby completing that portion of the building which is being erected in memory of the late Archbishop Benson. At the conclusion of the work £159,000 will have been spent on the cathedral, and there will only remain to be added the great central tower and two western towers, estimated to cost a further £15,000.

The Restoration Works at Pluscarden Priory have happily been stopped.

Mr. Henry Andrew Harper, a well-known painter of pictures of Jerusalem and the Holy Land, died recently.

New County Schools at Hengoed have been opened for girls. Messrs. James and Morgan, of Cardiff, are the architects.

A Bust of the Queen, by Mr. E. Onslow Ford, R.A., has been placed in the saloon of the Mansion House, City, E.C.

St. John-the-Baptist Church, Great Marlborough Street, W., has had a new pulpit, screen, and choir stalls added.

The Tooting Bec Asylum, S.W., is to be enlarged by the addition of receiving home for children, from plans by Messrs. A. and C. Harston.

The Rhosybol Board School, Anglesea, is being warmed and ventilated by means of Shorland's patent Manchester grates, supplied by Messrs E. H. Shorland and Brother, of Manchester.

A Memorial to Sir Thomas Dyke Acland is proposed to be placed at Oxford in the shape of a bust or tablet. Subscriptions should be sent to the London and County Bank, Oxford, or to Prof. J. A. Stewart, Christ Church, Oxford.

The William Black Memorial Tower is being erected on Duart Point, in the Sound of Mull, at an estimated cost of £1,563. Mr. R. S. Leiper, R.S.A., is the architect. The lighting will be by compressed gas contained in a tank under the light, which will require no attention, but continues night and day.

Suggested University for the North.—Lord Barnard formally opened last week the new science buildings, costing over £4,000, attached to the North-Eastern County School, Barnard Castle. In the course of his speech he advocated the endowment of a University for the north of England similar to the Birmingham University.

Collapse of Buildings at West Hampstead.—Last week the centre of a large block of shops and flats in course of erection in Mill Lane, West Hampstead, collapsed, and the front of the buildings, which had reached the third storey, fell to the ground. The workmen engaged on the building had fortunately not arrived at the time of the collapse.

"Peggotty's Hut," Great Yarmouth, immortalised by Charles Dickens in "David Copperfield," is to be sold to-morrow by public auction. This historic house, which stands on the site of the "Old Boat," is a great attraction to visitors during the summer months. Original portions of the wood, also the two windows of the boat, are still in possession of the present occupier.

Testing of Weights and Measures.—The Bristol Master Builders' Association recently had under consideration the question of testing weights and measures, and a copy of the local regulations prepared by the chief inspector, Mr. Frederick Newton, are now being issued to the members. The method of procedure adopted has saved the department a good deal of unpleasantness which would have arisen had the question been approached in any other way.

All Hallows Church, Blackborough, has had a new spire added, the old spire having become both unsightly and dangerous. The old spire ran straight up from the lower base, of the shape known as a "brooch." Under the new scheme a tower, with battlements, has first been erected. The tower has a lead flat, and from this on iron girders the spire proceeds, and is built to about the same height as the old one. The church stands on a hill nearly a thousand feet high, and the spire is consequently a landmark for miles around. The new spire is what is known as a "shingle" spire made of heart of oak and steel frame, plated with lead. A trap door opens to the lead flat, so that there will be easy access for future repairs without the necessity of erecting costly scaffolding, as had to be done on this occasion. Within the tower a new Council Chamber has been made for the use of the Church Council.

New Patents.

These patents are open to opposition until December 17th.

1899.—Wall Decoration.—24,516. A. E. HORTON, Bristol Street, Birmingham. The wall must have a smooth clean surface, and is first given the tint desired to form the background. A piece of lace, muslin, or similar material is then dipped into an adhesive and spread over the wall surface. The textile material may be woven in colours.

1900.—Self-lighting Gas Burners.—12,390, H. E. GRAY, 191 Fifty-fifth Street, Brooklyn, U.S.A. The burner has a lever, pivoted in the centre, with a chain attached at each end, and a pivoted arm carrying a piece of material which becomes incandescent when the gas impinges on it. Ignition takes place only when the gas is partly turned on; when the gas is full on the movable arm is automatically carried away from the light.

Water or Sewage Purification.—12,861. H. H. LAKE, 45 Southampton Buildings, London, W.C. (communicated by the Jewell Export Filter Company, 15 Broad Street, New York). This continuous process for the purification of water and other liquids is as follows:—Generating sulphurous oxide, passing the oxide into water, passing the sulphurous acid so formed over iron, oxidising the resulting solution, subjecting it to the action of a suitable precipitant, and separating the water from the resulting precipitate.

Smoke-consuming Furnaces.—14,828. G. SCHNEIDER, 4 Stubenranchstrasse, Schoneberg, Berlin, and G. DERTZ, 8 Quellhöfe, Cassel, Germany. The fuel is introduced from below, so that the smoke and gases given off are consumed by the incandescent layer above. The feeding is accomplished by a hinged box under the grate having a slide at the bottom. The fuel is passed in at the side and is then pushed up into the grate.

The following specifications were published on Saturday last, and are open to opposition until December 24th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—21,931, BURLEY AND ROGERS, fasteners for lamps, doors, &c. 22,606, DOULTON, gas and water-supply valves for water heaters. 23,112, SQUIRES, garden tiles. 23,976, MATTHIAS, smoke-consuming apparatus. 24,038, ARSCHAOULOFF, vertical sliding water-tight doors. 24,080, SLOAN (*Martin*), direct-acting pumps. 24,873, DAVIDSON, centrifugal fans and pumps. 24,952, THOMAS, means for affixing corrugated sheets of metal to roofs. 24,973, BELDAM AND COLES, fire sprinklers. 24,993, WEST, syphon flushing-cisterns. 25,028, PAGE (*International Metal Lath Company*), expanded metal structures. 25,089, BEASLEY, BEASLEY junior, AND BEASLEY, hack-cap for use in brickmaking.

1900.—586, TURNBULL, stop valves. 5,524, SMITH, painter's tool. 11,553, STEPHENS, keyhole guards. 12,524, PETREANO AND COMPAGNIE GEREBALE D'INCANDESCENCE PAR LE PETROLE ET L'ALCOHOL, burner for heating or lighting purposes. 13,367, OUSEY (*Globe-Wernicke Company*), sliding doors for book and other cases. 14,260, LANGE, cutters for worming wood screws. 15,059, PURNELL, firegrates. 16,167, METZ, paving of roads and other surfaces. 16,452, BÖRNER AND SCHURK, handles for tools. 16,473, PIKHART, incandescent mantles. 16,636, WEBER, angle-irons. 16,650, PETER, vices.

The Carnot Monument at Lyons, recently unveiled by President Loubet, is of gigantic proportions. A statue of M. Carnot stands against an obelisk, surmounted by a winged figure symbolical of France. At the base are figures of two youths bearing the escutcheons of Cronstadt and Toulon, while a feminine figure representing Lyons lays a funeral wreath at Carnot's feet. The memorial is the work of MM. Naudin and Grauquie.

THE ARCHITECTURAL ASSOCIATION.

THE LEGAL POSITION OF THE ARCHITECT.

BY L. L. MACASSEY.

A MEETING of this Association was held last Friday night, Mr. W. H. Seth-Smith, President, in the chair. The minutes having been read and confirmed, the following gentlemen were elected members:—Messrs. P. J. Bartlett, R. M. E. Carey, C. M. Childs, W. L. Clarke, H. A. Coldman, P. M. Collcutt, F. J. Cox, R. T. Congreve, W. S. Dakers, J. W. H. Farrow, S. T. Hennell, R. M. F. Huddart, W. C. Lemaitre, A. C. MacGeorge, R. H. Nicol, C. E. Power, E. T. L. Smith and F. Worrow.

On the motion of Mr. Seth-Smith, a vote of condolence with the family of the late Mr. William Young, F.R.I.B.A., in their bereavement was passed.

The following paper was then read by Mr. L. L. Macassey, jun., who had put it in form from notes prepared by his father, Mr. L. L. Macassey, who was not able to attend on account of illness:—

The capacities in which an architect requires to act are numerous and carry responsibility. At times he is called on not only to advise his client on matters of architectural moment, but often compelled to be a quasi-legal adviser and constantly obliged to assume the *rôle* of arbitrator between his employer and those engaged in carrying out his designs. In each capacity the law invests his actions with different legal consequences with which every architect should be acquainted. Members of the profession are presumed, in the eyes of the law, to be thoroughly versed in all matters requisite for properly advising their clients. "The public profession of an art," said Mr. Justice Willes, in *Harmer* v. *Cornelius*, 28 L.J.C.P. 85, "is a representation and undertaking to all the world that the professor possesses the requisite ability and skill." Indeed, the great principle of English law applicable all to such professions is that the architect must

Display Reasonable Skill and Care,

and if his employer suffer damage by reason of his failure so to do, for it the architect will be held responsible. There are in reality but few decisions bearing directly on the liability of architects, for the honour of the profession has been singularly well maintained. The knowledge of legal relations is essential to every architect. It is, indeed, a part of the reasonable care and skill he is obliged to possess. Without it he cannot fail to put himself and his employer in many injurious positions.

Now the employment of an architect may be divided under two main heads: his employment as a skilled adviser to his client and his employment during the execution of works as an agent of the client. Both branches of service come under the function of contract.

As a Skilled Adviser

the architect may be employed to give evidence, to make valuations of property, to act as arbitrator, and to prepare designs for intended buildings; and the latter is most frequently the form his employment takes. When, however, the buildings come to be erected, a contractor is generally called in, and as between the building owner and the contractor the architect acts as agent.

In dealing with the duties of the architect, reference must first be made to the retainer, for often the validity of his agency depends on his being properly retained. In most transactions between employer and architect

A Valid Contract

can generally be implied from the course of business letters between the parties, and if no terms are arranged the architect will be entitled to reasonable remuneration. It is always best, however, to have the conditions of service and the terms of payment settled before the work begins, and so avoid misunderstandings. A short letter from the architect reciting the terms will do, for, even though not acknowledged, the employer is legally bound if he acquiesces and allows the work to go on.

When, however, the employment will last for a year, the agreement should be in writing and signed by the employer (21 Car. II., c. 3, s. 4), the provision made by the Statute of Frauds. But the mere fact that the employment has extended beyond a year will not of itself bring the case within the statute. In fact, to make the Act apply, it must appear from the terms and subject matter of the agreement that the employment will not be completed within the year (*Peter* v. *Compton*, Skin 353), and it should also be noted that an agent of the employer, if duly authorised, may sign for him.

In cases where an architect is employed by a corporation, his retainer must be of a more formal character than when a private individual is the employer. As a general rule, contracts with corporations are only binding when under seal. Thus it has been held that a medical officer employed by a Board of Guardians must be appointed under seal (*Dyte* v. *St. Pancras Board of Guardians*, 27 L.T. 342).

But a contract not under seal may be binding upon a corporation in certain cases, that is, if it is with respect to matters necessary or incidental to the functions or business which the corporation has been created to carry on. What these matters are it is somewhat difficult at times to decide. In *Nicholson* v. *Bradfield Guardians* (L.R. 1, Q.B. 620) it was held that a dealer who supplied coal to the workhouse under an agreement not under seal was entitled to recover the price. Probably thus an architect retained to do repairs would not require to be retained under seal by a corporation, but if to construct new buildings and works he would.

As regards contracts with local and sanitary authorities, reference must be made to Section 174 of the Public Health Act, 1875, which enacts as follows (38 & 39 Vic., c. 55, s. 174, s.s. 1):—"Every contract made with an urban authority whereof the value or amount exceeds £50 shall be in writing and sealed with the common seal of such authority." The decision in *Hunt* v. *Wimbledon Local Board* turned on this point (3 C.P.D. 208, 4 C.P.D. 48). The plaintiff had been employed by the Board's Surveyor under their express authority to prepare plans for new offices for the Board. When the tenders came in, however, it was found the lowest considerably exceeded the estimate. The scheme fell through, and on the plaintiff suing for his fees for the preparation of his plans the jury found that the offices were necessary for the purposes of the Board, and that the plans were necessary for the erection of their offices. But it was held by the Court that Sub-Section 1 of Section 174 of the Public Health Act, 1875, was mandatory, and *as the amount was over* £50, and the contract not under seal, the plaintiff could not recover.

But in *Younge and Co.* v. *Mayor, &c.*, of Royal Leamington Spa (8 App. Cas. 517), the defendants' engineer, with their approval and consent, called in the plaintiffs under the specification to finish up a contract abandoned by a former contractor. The work was completed and the defendant board got the benefit of it, but the plaintiffs failed to recover, as there was no contract under seal.

But Section 174 does not apply unless it is apparent at the outset that the amount of the work or the value of the services rendered will exceed £50. Thus, in *Eaton* v. *Basker* (7 Q.B.D. 529) a medical man agreed verbally with a Sanitary Authority to attend fever patients in tents at 5s. 3d. per tent per day. His bill ran up to £100. It was held that he was entitled to recover, as the contract was not one exceeding £50 and requiring a sealed agreement within the meaning of the Act, as at the time it was entered into the parties had not ascertained it would exceed that amount.

What, then, do these cases show us? Firstly, this, that an architect, to be

A Properly Authorised Agent,

should not accept a retainer to prepare plans for a Corporation or Local Authority unless under their common seal, if in the latter case his percentage or fees exceed £50. He may find it impossible to sue for his fees, and in the carrying out of the works he may, as the agent of the Corporation or Local Authority, have perfectly *bonâ fide* made arrangements with builders and contractors which, however, his employers are in a position to repudiate, placing him in the undeserved position of having, in in the eyes of the law, acted as an agent without authority, and rendering himself liable to the builders or contractors.

Even at common law, apart from the Public Health Act, the Corporations or Local Authorities might disclaim all contracts, however small, he had made on their behalf, and an agent, though honestly acting in a believed authority, is liable under the rule in *Collen* v. *Wright* (8 E. & B. 647) and *Firbanks Exors.* v. *Humphreys* (18 Q.B.D.(C.A.)62), which renders him personally liable. An architect may, however, if retained to advise at day fees, recover his fees against a Local Authority under *Eaton* v. *Basker*, although they do exceed £50.

The architect to a Local Authority, if he be a permanent official, may, however, be lawfully appointed under Section 189 of the Public Health Act by resolution entered on the minutes, as in *Smith* v. *Hirst*, 23 L.T. 665, and in such a way appointed may act as the Local Authority's agent without fear of consequences.

So an architect may be validly appointed or merely temporarily retained by School Boards acting under the Elementary Education Act, 1870, Section 35, and Rule 7, Schedule III., by a minute of the Board, countersigned by the chairman and by the clerk (*Scott* v. *Great and Little Clifton School Board*, 14 Q.B.D. 500).

At the outset I pointed out that the architect who holds himself out for and accepts employment must possess, and bring to bear upon the discharge of his duties, a reasonable amount of

Skill and Care.

But the obligation does not apply alone to architects. Solicitors, doctors, dentists, and many other persons engaged in professional and technical matters are subject to the same liability. The question then arises, What is a reasonable amount of skill which must be possessed by an architect? And the answer to this is not very satisfactory. No general rule can be laid down. The circumstances of each case must be taken into consideration. It is not enough to act to the best of one's skill and ability, one must act in a skilful manner (*Jones* v. *Bird*, 5 B. & A., 845). What would be a skilful manner under the particular circumstances seems to involve much greater knowledge and ability to-day than it did 50 years ago. The law considers the advance of science and human requirements. But before going into details let me mention one exception. If an employer accepts the services of an architect to carry out certain work, and knows that the architect has had but limited experience and training, he does so at his own risk. And if by reason of the inexperience of the architect damage occurs, the employer cannot, in the absence of negligence, hold the architect liable therefor. When, however, the fact of an architect's incompetence for the work becomes known to his employers, they are justified in dispensing with his services before the expiration of his engagement (*Harmer* v. *Cornelius*, 28 L.J.C.P., 85).

As the first illustration of absence of reasonable care and skill, one may deal with the introduction into a design of some novel invention the success of which has never been tried, or the undertaking, in the first instance, of work of a very doubtful result. In the case of the doctor or solicitor there is no implied warranty as to results. The doctor may do his best and the patient may die, the solicitor may take every needful step and yet lose his case. But these contingencies do not come to the aid of the architect; he is

Bound to Avoid Experiment

at the expense of his clients; and unless he sees his way to a successful result the work should not go on. In *Duncan* v. *Blundell*, 3 Stark 6, 5 M. & P., 548, Mr. Justice Bayley said:—"A professional man should not undertake work when he does not know whether he can succeed or not." The law, however, is very indefinite as to what length an architect may go in doubtful work. Direct authorities are wanting, but reasoning from analogous decisions discloses the principle that to be free from liability he should acquaint his employer fully with the hazardous nature of the work, and obtain his consent thereto, and satisfy himself, after in

vestigation, that with the adoption of proper methods the work may be carried out successfully. In an old case of *Slater* v. *Baker and Stapleton*, 2 Wilson, 359, where surgeons had used a new instrument for operating with disastrous results, the Court said "this was the first experiment made with this new instrument, and if it was it was a rash action," and allowed the action. But in case of an action against an architect in respect of unsuccessful work, it would appear from *Chapman* v. *Walton* (10 Bing, 63) that the fact that he took the steps that all architects in his position would have taken will be a good defence. A clear distinction should be drawn between mistakes in policy on the part of the employer and

Incompetent Procedure

on the part of the architect. A wooden building like a Norwegian hotel is much cheaper than a stone erection; if the architect builds it of wood according to instructions and of proper dimensions he is not answerable if it does not stand the weather.

As sometimes happens, the employer is dissatisfied after the completion of the work with the result of the design, and tries to throw responsibility on the architect. What is the position of the architect? With respect to all matters of policy on which the client is competent to form an opinion, as, for example, the arrangement of particuiar rooms in a house, and of which he has approved, he is estopped from turning round afterwards upon the architect and charging him with want of skill. But the employer is not deemed to be competent to determine minute matters of detail, such, for instance, as to whether or not particular members are of proper scantling. Should girders break or walls crack from causes that the architect ought to have foreseen, the latter will be liable for want of reasonable skill.

The position of the architect

In respect of Plans

prepared by him is of special importance, and how he is affected by any errors or insufficiencies either in them or the specification. The case of *Thorn* v. *The Lord Mayor of London*, 1 App., Cas. 120, may be regarded as the leading authority. There the facts were these:—The plaintiff had contracted with the Corporation of London to build a bridge across the Thames according to the plans of the City Engineer. Certain caissons for the pier foundation were included in the work, and these the contractor found he could not construct according to the plans and specification Another method, with the consent of the engineer, had to be adopted, and the contractor sued for the extra expenditure he had so incurred. It was held, however, that he could not succeed, as there was no warranty. on the part of the defendants that the works as proposed were capable of being carried into execution. The usual clauses were in the specification. It will thus be seen that, under ordinary plans and specifications, architects as against contractors cannot be made liable for their insufficiency. So that if a contractor undertakes to do a thing that is impossible at the outset, he may refuse to carry out the contract on the ground of impossibility of performance according to the decided cases; yet where he has once entered on and completed the work, he cannot claim in respect of any extra expense occasioned by the work being impossible or impracticable.

Liability for Defective Drawings.

The liability of the architect towards his employer for defective drawings is, of course, different, and we must distinguish defective drawings by reason of the work being infeasible, and defective drawings prepared in a careless manner. An architect, in the absence of special agreement, is bound to make sufficient preliminary investigation to satisfy himself that his proposals are practicable. Thus, in the case of *Moneypenny* v. *Hartland*, 2 C. & P., 378, the plaintiff had been employed to prepare an estimate and other particulars for a committee proposing to erect a bridge. He relied on the borings that had been taken by a surveyor previously employed by the committee, which turned out incorrect. The estimates were exceeded in consequence, and the plaintiff, when he sued for his fees, failed to recover. It is rather difficult to say whether the committee would have succeeded in an action against the architect. Could they have shown appreciable damage, I am inclined to think they could, for his neglect of ordinary skill and care.

In respect of defects in the drawings arising out of careless preparation, it would probably only be when the employer had been put to extra expense thereby that he would take proceedings against an architect. This, as we have seen, is not likely to happen. But if it should, the architect is undoubtedly liable for want of skill and care.

As against the public few cases have occurred in which architects have been held

Liable for Failure

of their designs. A case is *Mosdell* v. *Mitchell and others* ("Times," January 20th, 1891), in which the widow of a workman brought an action under Lord Campbell's Act against a building owner, his contractor and architect, for the loss of her husband, who was killed by the walls of a house falling upon him, which were too light to bear the strain. The house had been designed by the defendant architect for the defendant builder. During the hearing the jury, on the suggestion of the judge, stopped the case against the building owner, and gave a verdict for £500 against the builder and architect jointly.

As illustrative of the care that the law exacts from an architect in his capacity of skilful adviser, one may mention the case of *Crabb and others* v. *Brinsley* (5 T.L.R. 14), in which the defendant had been retained to advise on the character and condition of certain houses in Holborn proposed as security for a mortgage. The defendant reported that the houses were good security. The plaintiffs made an advance of £1,500, but the premises were afterwards sold for £410. There were two actions, and in the second action the plaintiffs recovered the full amount of their advance, viz., £1,500, as against the defendant architects. The law appears well settled that the architect must bring to the discharge of his duty a reasonable amount of skill and care.

We may now assume that the architect has completed his drawings and specifications for some intended work, and that the building owner has approved of the documents and is desirous of obtaining tenders. The architect, as a rule, is called upon to investigate the character of the different tenders submitted, and his duty is to advise impartially. In a case of *Miller* v. *Wilson*, reported in the "Building News" of August 6th, 1886, the plaintiff, a building owner, sued an architect for advising him to accept a particular tender under which alterations to his house were carried out, and which were the highest of those sent in. After a great deal of conflicting evidence on both sides, eventually the jury found for the defendant architect. Plainly, an architect's duty is to advise which of the firms who have tendered are most likely to do the work the cheapest, but in the most satisfactory manner, and bring it to a satisfactory conclusion.

With the acceptance of a tender by the employer, and the entering into of a contract, the architect enters upon a wider sphere of duty in acting as his employer's agent. His duty, then, is to faithfully carry out the work according to the plans and specifications, and

To Exercise a Competent Supervision

to ensure satisfactory workmanship and materials being obtained.

An architect during the construction of the works has not authority to deviate from plans or specification in the slightest without his employers' consent. When no express authority is given, an architect can only bind his employers in respect of acts done or orders given in the general course of his employment, and these are confined to such as are absolutely necessary for carrying out the work. The authority of the architect is really but of very limited extent. In the words of Chief Baron Alexander in *Rex* v. *Peto*, the 1 Y. and J. 37, he is a "person who ought to be in general, but an onlooker of the owner to see that the work is accurately performed." *Cooper* v. *Langdon* (9 M.W. 60) is an instructive case. There, according to the drawings and specifications, a certain wall was to be of brick, for which stone was substituted by the builder. The building owner took action for breach of contract and succeeded. The defendants claimed that he made the alteration at the instigation of the architect, but there was no authority shown on the part of the architect to bind his employer in respect of any deviations from the drawings.

The authority to make alterations or additions is usually conferred by the building contract, when it is conferred at all, and the architect must keep strictly within its terms. Thus in *Rex* v. *Peto* (quoted above) the architect had had the power to order "additions or omissions." The work consisted in building a custom house with piled foundations. The architect had the house built without piled foundations, and it was held that this was not an omission, but, in reality, a variation which was not in the power of the architect to order.

A matter of great importance is the question of quantities, and on this a few observations may be offered. It is extremely doubtful whether an architect is allowed

To Retain a Quantity Surveyor

without express authority from his employer. Much depends on the terms of the architect's retainer. Thus, in *Waghorne* v. *Wimbledon Local Board* ("Times," June 4th, 1877), the defendant board instructed their surveyor to prepare plans and specifications and procure tenders for the erection of a mortuary chapel. The surveyor instructed the plaintiff to take out the quantities. He did so, and sent in his bill in the ordinary way. The Board refused to pay, but the Court held that, as the Board had instructed their surveyor to procure tenders, and as tenders could not have been submitted without bills of quantities, there was implied authority to the surveyor to retain a quantity surveyor.

Where, however, the architect is not directed to procure tenders, it is exceedingly questionable whether, apart from a distinct custom in the profession, an architect, on his own initiation, should retain a quantity surveyor; in fact, it is so doubtful that it is much better not to do so (*Moon* v. *Guardians of Witney Union*, 3 Bing. N.C. 114, cf. *Evans* v. *Carte*, "Times," May 28th, 1882). For should the architect retain a quantity surveyor without authority, he will be personally liable for that gentleman's reasonable charges, and it matters not that he retained him in perfect good faith and convinced of his authority to do so (*Collen* v. *Wright*, 8 E. and B., 647). In a case, *Gordon* v. *Blackburne* ("The Builder," February 1st, 1879), the defendant, an architect, had requested the plaintiff to take out quantities for a building he had been instructed to prepare plans for. The quantity surveyor did so, and applied to the architect for payment, by whom he was referred to his employers. He then proceeded against the architect, and recovered his fees.

The architect should not prepare the quantities himself. It is objectionable for many reasons, as the quantities are often

Paid for by the Builder.

The general law prohibits an agent from making any profit out of his agency apart from his own proper remuneration by his employers. And it is only a custom to the effect stated that would enable an architect to receive any money from the builder in respect of quantities.

In the case of inaccuracies in bills of quantities, what are the liabilities of quantity surveyor and architect? The quantity surveyor is appointed by the owner. To the owner, then, and to him alone is the quantity surveyor responsible at all. There is no privity between the quantity surveyor and the contractor, and therefore no liability to the contractor, apart from fraudulent misrepresentation, although, as was held in *North* v. *Bassett* (1 Q.B. 333), there may be a reasonable and good custom that the builder should pay the quantity surveyor's charges.

Whether the architect or a quantity surveyor takes out the quantities, it is to their employer that they will be liable, and to him only, for negligence and want of care. But as the judge remarked in *Priestly* v. *Stone* (4 "Times" L.R.

730), quantity surveyors are not liable apart from negligence. What they do is to submit their quantities as the result of their calculations, and to the best of their belief correct. There is the obligation on the builder taking those quantities to satisfy himself of their accuracy.

The two principles of law governing the liability of architects, viz., the application of reasonable skill and care, and their keeping within the limits of their authority as agents, must now be applied more immediately to their conduct during the execution of works.

At such a time an architect's duty is to exercise a proper supervision, so that the employer gets as good a building as he bargained for. In *Ellisen* v. *Lawrie* ("Times," February 19th, 1878), owing to the improper attention given by an architect to the laying and jointing of sewer pipes in connection with a dwelling-house, foul gases penetrated into the residence, causing illness in the family. The plaintiff, the owner, sued the architect for the cost of repairs and for medical expenses, and succeeded in his action. Of course, the question of what constitutes proper supervision must be left to the discretion of the architect, who knows the character of the work, and more especially the character of the contractor engaged upon its execution.

The liability of the architect in respect of

Alterations and Omissions

has already been dealt with. It should be mentioned that he has no authority of himself to call in a quantity surveyor, as is often done, to measure up deviations and extras. That was the course adopted in *Plimsaul* v. *Lord Kilmorey* (1 T.L.R., 48) by the architect in respect of building operations at St. James's Theatre. It was held that he had no right to do so, and that even if there was a custom for the architect to employ a quantity surveyor it could not reasonably apply to the measuring up of extras.

Dealing with the question of extras—a most trying one often to architects—most specifications provide that extra work shall only be executed on being ordered in writing by the employer or the architect. No definition exists of what constitutes extras, though many have been suggested, and the builder may refuse to carry out certain items of work, claiming them as extras, unless on written authority, items which the architect may consider within the contract. But an order in writing may be given under protest and will not be construed as against the architect or the employer as admitting the contractor's contention. The position of the architect as against the contractor is this: If the specification provides for a written order, a written order there must be before the contractor can claim payment (*Thames Iron Works Company* v. *Royal Mail Steam Packet Company* (13 C.B. [N.S.] 358), and if a contractor executes work with this provision without a written order, he has, if there has been no waiver of the condition, no redress against anyone. But supposing the specification is silent, then the architect cannot without express authority from his employer order extra work. If he does so, and holds himself out as possessing, or acts without that necessary authority, he renders himself personally liable to the contractor in respect of the extra work so ordered (*Collen* v. *Wright*).

Passing on to the architect's duty in respect of

Measuring up,

that involves the same application of reasonable care and skill. The accuracy of the work must be considered in respect to the magnitude of the job, and is altogether a question of degree. Thus in *Corbett* v. *Richmond and Chandler*, reported in the "Building News," May 18th, 1888, the plaintiff was an architect, and sued the defendants (his employers) for balance of his commission in respect of the erection of certain premises in Manchester. The defendants resisted on the ground of the architect's negligence in measuring up work with the result that the contractors were paid £537 more than they were entitled to. The official referee to whom the Judge referred the case said £537 on £10,000, the value of the premises amounted to only ¾ per cent., and with only such a difference between the defendants' and the plaintiff's figure on such a job, it was absolute nonsense to charge an architect with negligence. He had never known a case in which negligence was charged against a professional man on such insufficient grounds. Towards the contractor the architect is not liable at all in respect of measuring up except on the ground of fraud.

Much the same state of things exists in regard to certificates. To the employer the architect is responsible for negligence in granting certificates, whether it be a progress or a final certificate; and the fact that by the terms of a building contract a final certificate is to bind both builder and employer, does not bind architect and employer. Thus, in *Rogers* v. *James* (8 T.L.R. 67) the plaintiff was an architect who sought to recover a balance of fees in connection with the supervision of some houses. The defendant (his employer) counterclaimed for negligence, in that the architect had not insisted on the builder putting in certain concrete in foundations. The architect pleaded that he had deducted the value thereof from the balance of the contract money payable to the contractor under his final certificate, and that it, under the usual clause in the specification, was binding on both employer and builder. The jury found that the plaintiff had been negligent. The Judge held, and his view was maintained by the Court of Appeal, that the clause binding employer and builder did not apply as between architect and employer.

When the issue of the architect's certificate is a condition precedent to the payment of the contractor, an architect is often perplexed to know how he stands if, from reasons of dissatisfaction with the work, he is unable honestly to grant the certificate. Is he liable to an action at the hands of the contractor? It must be remembered in connection with this that the architect is in no way the servant of the contractor, and owes him no duty different from that which he owes to all mankind. The case of *Le Lievre* v. *Gould* (1 Q.B. 491), was an action against an architect for negligence in discharging his duty by. The plaintiff was a third party who had not retained or paid the architect, and, moreover, the negligence was practically admitted. But the action failed. Lord Esher's judgment contained the following sentences:—"What duty is there where there is no relation between the parties by contract? In the absence of contract an action for negligence cannot be maintained when there is no fraud. And in *Stevenson* v. *Watson* (4 C.P.D., 148) the plaintiffs, certain builders, took action against the defendant architect in respect of his certificate being insufficient, alleging that he did not exercise care and skill in ascertaining the amount due to them, but not alleging fraud. It was held that the defendant in granting certificates was not liable for want of care or skill to the contractors. He was only bound to give an honest decision.

So that, therefore, an architect generally is only liable to a contractor in point of fraud, whether in respect of refusal to grant certificates or delay in granting them, or approval or condemnation of materials or workmanship, and other such matters. Lord Herschel very clearly and explicitly explains in *Peek* v. *Derry* (14 Ap. Cas. 374) what is fraud. "Fraud," he says, "is proved when it is shown that a false representation has been made (1) knowingly, or (2) without belief in its truth, or (3) recklessly, careless whether it be true or false.

If, therefore, an architect believes in the justice of his cause, let him refuse a certificate fearless of consequence, but on grounds, however, that he can stand over should the contractor proceed for a mandatory injunction to restrain the employer from keeping him out of his money.

There is an interesting case, that of *Ludbrooke* v. *Barrett* (46 L.J., C.P., 798), to illustrate what was held to amount to

Fraud on the Part of the Architect

in refusing to grant a certificate. The plaintiffs, being builders, had agreed to build certain buildings for one Ridgway on the condition that they should be paid on the defendant's certificate when the buildings were erected to his satisfaction. It was found that the architect had an interest in the matter, and that he had colluded fraudulently with the building-owner in refusing the certificate, and the action was allowed.

The architect has often, as was mentioned, to occupy the somewhat inconvenient

Position of Arbitrator

between the contractor and the employer. Acting as such, he is in the position of a quasi-judge, and, as such, is not liable to either the employer or the contractor for negligence or want of skill in making his award. He is, of course, personally liable for fraud, and that to all parties injured by his wrongful acts. In the *Tharsis Sulphur Company* v. *Loftus* (L.R. 8, C.P., 1), the defendant, an average adjuster, was retained by the plaintiffs to settle and adjust the proportion which the ship and cargo respectively were to bear the losses incurred during the voyage. When he had made his award the plaintiffs, in spite of their undertaking to abide by his decision, brought an action against him alleging negligence in making his award. It was held, however, that the action would not lie, and see also *Pappa* v. *Rose* (L.R., 7 C.P., 32 and 525).

Architects in their professional career are frequently and inevitably made the recipients of confidential information respecting the affairs of their clients, and not infrequently at some other stage of their career find themselves in the position of opponents to their former employers. It is not easy to decide what is confidential information, but, be it what it may, the decision in *Robb* v. *Green* (A.C., 315) and the words of Lord Justice Smith are imperative:—"It is a necessary implication which must be grafted on a contract of service that the servant undertakes to serve his master with good faith and fidelity, and it is a breach of this condition to use during or after the period of service confidential information acquired during it adversely to the employer or for the servant's own benefit." Plans belonging to a late employer, for instance, would be confidential, and if submitted to a new employer the Courts would issue an injunction against any architect so acting, and would compensate his late employer by damages for any injury incurred thereby. But where there is nothing confidential in the information, where it is merely a compilation of facts in everyone's power to make, if possessed of the requisite ability, there is nothing to prevent an architect using that for the benefit of himself or of his new clients.

It was mentioned at the outset that the law deems an architect to be acquainted with its general principles to ensure an observance of his advice by his client being free from injurious consequences. The precise extent of this knowledge is not clear. From *Jenkins* v. *Betham* (15 C.B., 188), we may gain some information. The defendants were engaged by the plaintiff, on his appointment to a living, to value dilapidations. They valued the dilapidations at too low a figure, because of their ignorance of the legal difference between outgoing and incoming incumbents, which they admitted. The Judge at the trial directed the jury that the defendants could not be held unskilful for not knowing the law as a lawyer did, but that they should be liable if they did not display such a knowledge of it as was ordinarily current. On a motion for a new trial the Court held that the defendants should have known the broad distinction existing between outgoing and incoming incumbents. So it seems that an architect may be required to know the broad principles of law applicable to matters within his everyday business, such as ancient lights and the right to vertical and lateral support, and that for damage arising to his employer through his ignorance of such questions he will be held responsible.

In conclusion it may be observed that many of the difficulties experienced and responsibilities undertaken by architects are such as with properly drawn specifications and carefully prepared plans should not arise.

THE DISCUSSION.

Mr. A. HARSTON, in opening the discussion on the paper, recommended a book on this subject, of which Mr. L. L. Macassey was part author. He advised architects never to give

an order in their own name; if they did not instruct the builder to order the goods, they had better order as agents for their clients.

Mr. HAMPDEN W. PRATT proposed a vote of thanks to Mr. Macassey, which was seconded by Mr. E. GREENOP.

Mr. H. T. HARE said, in regard to ownership of drawings, that he did not think the building owner could claim the preliminary sketches, as the architect was merely engaged to complete a building.

Mr. A. T. BOLTON thought it was difficult to get the legal profession not to look upon drawings as documents, as they were signed and therefore considered to belong to the owner. It was possible to erect a building without any drawings on paper whatever. The architect was usually looked upon as a policeman to keep the builder straight, but in the best sense he was really chief of the workmen, and should co-operate with the builder.

Mr. F. G. F. Hooper, F. J. Osborne Smith, C. H. Brodie, and Mr. W. H. Seth-Smith also spoke.

Mr. MACASSEY, jun., said, in reply, that it would be well, perhaps, if they had a definition of an agent. An agent was a person appointed by someone to act for him, and the acts of the agent were considered the acts of the principal. He might be a special agent or a general agent. An architect was the former. An architect must either act as agent for the builder, for the employer, or as a go-between. In the speaker's opinion it was most unsatisfactory, if not absolutely impossible, to act as a go-between; and it followed that you must have an architect acting as the agent for the principal. An architect had not authority to order extras himself unless he had the express authority of his client. He thought that it was becoming more and more necessary for architects to take steps to form the profession into a close one and obtain enactments for their protection. The great difference between the law of France and that of England was that in the former it was codified, whereas here we had to depend on decisions in previous cases.

The vote of thanks to Mr. Macassey was then accorded.

Under Discussion.

LOCKS—ANCIENT AND MODERN.

THIS was the title of the lecture delivered by Mr. H. W. Chubb before the Architectural Association of Ireland on Tuesday in last week. Commencing with the simplest form of security—a simple bar and pin—the lecturer referred to Egyptian locks, in wood, and Roman locks, in bronze and iron, which, he said, exhibited an increased degree of complication. The lecturer showed models of curious Chinese and Japanese padlocks at present in use. Early English locks were more in the form of those in modern use. Referring to a diagram of a beautifully designed key of the Renaissance period, he said that at that time before an apprentice was admitted to the Guild of Locksmiths, he was obliged to make a very fine key to be presented to the chief craftsman; and one or two years was often spent by the apprentice in making a single key. A characteristic of some German locks of the Middle Ages was that they had projecting guides to enable a person to find the keyhole when he came home on a dark night.

NORMAN MASONRY IN CORNWALL.

IN the course of a lecture recently delivered at the Plymouth Institution on "The Norman Remains in Cornwall" Mr. Edmund Sedding said that the Western peninsula had retained much of its primæval character undisturbed by the immense increase in population which has so much affected other counties in Old England. The mediæval buildings partook of the savagery of the grand natural surroundings. England became one great workshop under the influence of the Normans, whose noble buildings entirely superseded the lowly Saxon work in Cornwall, where none was now to be found. Mr. Sedding selected the churches of Morwenstow, Tintagel, North Petherwin, and St. Clether as illustrating the best and most characteristic work of the Normans. The work at St. Germains was the earliest and grandest, but in detail Morwenstow's north arcade had no equal in the county. The church at Tintagel had withstood the fury of the North Cornish gales for six centuries. The portions of the north arcade at St. Clether and North Petherwin are of much interest, but as in the case of the other two churches mentioned, they are very inaccessible. These arcades and the one at Morwenstow had circular columns with narrow jointed stones, with an average diameter of 30in. All the Norman capitals in the county had the square abacus to their capitals, but the caps at Morwenstow were circular and enriched by chevron work, shallow worked, like the Danish worked their details at this time. The arches at St. Clether and North Petherwin are pointed, as in the case at St. Germains, and were executed about 30 years later. The Normans were workers in freestone, which may explain the reason why so little exterior masonry is left in the county, with its ruthless winds and driving rain which soon causes decay, unless the stone is carefully watched and repaired by wise treatment. There are several doorways and fonts left, and the lecturer appealed for their preservation, as recording the faith and love of ages of craftsmen whose work as builders must ever stand prominent and be worthy of admiration.

BY-PATHS IN ARCHITECTURE.

UNDER the auspices of the students' section of the Dundee Institute of Architecture, Mr. G. S. Aitken, F.S.A, Edinburgh, lectured recently on "Some By-paths in Architecture." The lecturer, after prefatory remarks, submitted that a knowledge of landscape gardening was a very good thing for an architect to have. It was a trite remark that the house an architect built might be made or marred by its surroundings. Mr. Aitken then proceeded to give hints as to the laying out of grounds, commenting on the various trees and shrubs which might be employed. Passing on to speak of flower gardens, he said it would generally be conceded that while a certain amount of irregularity of plan and contour was advisable on that part of the grounds furthest away from a house, the immediately adjacent parts should be of a formal character, and in consonance with the architecture of the building. That admitted, it would not be difficult to determine the arrangement of the flower borders. Another by-path which the architect could follow with much profit was that of geology, because it was absolutely impossible that he could be fully equipped for his profession or be a competent judge of the materials he was called upon to handle without some precise information as to their origin and constituents. Water-colour drawing formed another by-path in architecture. It was quite needless to prove that every architect should be a colourist. Archæology was another instructive by-path, and in speaking on this subject Mr. Aitken illustrated how much valuable knowledge could be acquired by the study of ruins and ancient buildings. He subsequently referred to the study of heraldry as being still another useful by-path for the architect, and concluded by stating that there were special reasons why the architect should make a study of music. His own work would acquire rhythm and grace, and his studies on the mechanical side of music would qualify him to speak with authority when called upon to do so. The architect should no more step aside when in the course of his practice he was called on to design an organ chamber in house or chapel, or to devise a space for the bells which were to ring out from tower or steeple, than that he should withdraw from the consideration of sanitation and such other departments which were too often considered mere by-paths in architecture. But any or all the by-paths to which he had referred were not to be so absorbingly followed as to interfere with the attention which was due to the weightier matters of skilful planning, soulful design, sound construction, and healthful arrangements.

THE CRAFTS AND ART OF BRICKWORK.

ON Thursday last the first meeting of the present session of the Sheffield Society of Architects was held, when Mr. Beresford Pite, F.R.I.B.A., read a paper on "The Crafts and Art of Brickwork." He said the importance to a designer of full acquaintance with the nature and properties of the materials for which he designs need not to be stated at length. In order to give expression in work to the special qualities of a material, his knowledge of it must not only be technical as to its nature and manufacture, but historical, so that its traditional uses and suitability may be considered and reflected in design. There is a necessary harmony and relation between the means employed and the end to be attained in architecture, as in every work of beauty.

Beautiful design, sound construction, and satisfactory materials are each necessary to good architecture. The different expression of a wall erected in stonework and another built of bricks is an illustration of the importance of the material artistically. In that of stonework, the stones, from their size and natural beauty, give the wall its character and expression. The material is natural, and may be in itself delightful; the working of it, the bonding and jointing, and the cement—all are certainly important, but secondary entirely to the stone in the interest of the structure. In a brick wall the material is of no great interest; in spite of the dictum of Vitruvius, it is mean and humble; the uniformity of the sizes of the bricks and their smallness have this effect, but the interest and beauty of finished brickwork is very great. The mortar which embeds and encloses each brick unit, the bonding, regularity, and evenness of the whole composed of so many units are each factors of interest. The mortar, or cementing material, plays a much more important part than in the wall of masonry. Together with the bricks, it forms a concrete amalgam, rather than a structure of squared blocks. This character can be readily seen in the remains of Roman brickwork in England, notably in the fine wall at Leicester.

Mediæval and Elizabethan brickwork had much the same effect, the mortar joints being broad, but the work of the Georgian period witnesses a change of feeling. A finer quality of brick, suitable for carving and moulding into architectural forms, was largely used, and with it a fine and delicate mortar joint, the amount of mortar revealed on the surface of the wall being of the smallest possible extent. This work has more the characteristics of minute masonry. The bonding and planning of the courses of bricks became of greater importance with the decline of mortar, the strength of such walling being dependent on the distribution of the weight and thrusts on the body of each brick and not on its joints, the adhesive quality of the mortar not being a constructive consideration. Modern brickwork is a practical compromise between the mediæval and Georgian methods; the mortar joint is neither thick nor thin, and consistent bonding is often neglected, the use of powerful mortar being expected to make amends for it. In brickwork there is scope for fine handicraft and much human interest; and even a garden wall may be rendered beautiful and have character. The quality of texture and surface, which is valuable and important in all great work, can be imparted by a sympathetic study of even brick and mortar; true sympathy with the material that he uses will prevent an architect from lapsing into anachronisms in designing features unsuitable for execution in brickwork, and will also provide the student with a new stimulant to the enthusiastic study of the elements of fine buildings.

Newport (I.W.) Competition.—We understand that Mr. W. V. Gough, of Bristol, and Mr. A. A. Burnett, F.S.I., of Southampton, have been awarded the premiums of £50 each for plans for the new Free Library, Technical Institute, and County Offices at Newport, Isle of Wight, the plans of the former being adopted, subject to alterations, at an estimated cost of £9,500. There were 54 competitors, and six plans were selected by the assessor (Colonel Edis, F.S.A.); the authors of the remaining four were:—Messrs. Houston and Houston, London; Mr. C. A. Sharpe, Westminster; Mr. H. Chatfield Clarke, London; and Mr. F. A. Tugwell, Scarborough.

R. I. B. A.

THE FORUM EXCAVATIONS.

AT the meeting of the Royal Institute of British Architects held on Monday evening last (the president, Mr. William Emerson, in the chair), a paper was read by Professor Lanciani, Hon. Corr. Member, on the "Architectural Results of the Latest Excavations in the Forum."

The lecturer explained that the remarkable success of these excavations in a district which had been so often searched and laid bare was due to the fact that former excavations had always stopped at the higher level of ruins. As soon as the pavement of a street, house, or public building had been exposed to view, they were asked to stop without being able to ascertain what was under those structures. As it was known that the Roman Forum and the region of the Sacra Via had been swept by fire and rebuilt at least four times under the Empire, it was at last determined to probe that sacred piece of ground down to the level of the virgin soil wherever it was possible to do so without injury to the higher and later structures. The results surpassed their most sanguine expectations, especially from the archæological and historical point of view. The architectural discoveries, too, though modest, nevertheless merited special notice. By means of a series of photographic lantern slides the lecturer conducted his audience over the Forum and the Sacra Via, starting from the Comitium. Nearly two years had elapsed since the finding of the monument which they had identified as the Heroon, or empty grave of Romulus. The controversy about the nature, date and object of the monument had been decided in their favour, and it was now admitted that this was really the identical monument raised in honour and in memory of Romulus at the time when Rome was still ruled by the kings. The deification of Romulus was not a late Greek fable, as some recent critics contend, but a fact proved conclusively by these recent discoveries. The Heroon is, or was, composed of six parts or elements—namely, (*a*) the cenotaph, or empty grave, (*b*) the two lions which guarded it on either side, (*c*) the honorary pillar, (*d*) the stone inscribed with the *lex loci*, (*e*) the altar, (*f*) the sacrificial horn. The whole group was found embedded in layers of sacrificial remains under the level of the Imperial Comitium. Its site was indicated by a square enclosure surrounded by a marble transerina and paved with black stone, the famous "lapis niger" of Festus and Varro. The cenotaph was found filled up with earth and decomposed organic remains, without any trace of a cinerarium or ossarium; this is in perfect accordance with the Roman tradition and the popular belief in the fate of Romulus. The interest of this chain of discoveries culminated in the inscribed stele or pyramid still standing after twenty-six centuries on the identical site on which it was set up at the time of King Hama and King Servius. The inscription engraved on this rough block of tufa has been given the place of honour among the 95,000 epigraphic documents which have been collected all through the Roman Empire for the *Corpus inscriptionem*. It precedes by a couple of centuries what was considered up to the date of its discovery to be the very oldest specimen of the Latin language and Latin palæography, the so-called cup of Drenos, now in the Berlin Museum.

Continuing along the Sacra Via, Professor Lianciani referred to the results of the geological exploration of the ground, showing how the primitive path, which was irregular and winding, had gradually been transformed until, as buildings were erected on either side, it took a definite shape and was made to turn four or five times at right angles. Coming to the newly-discovered monument, the Basilica Æmilia, the lecturer said they had learned by experience the possibility of this extraordinary fact: that a building of the first magnitude like the Basilica Æmilia, proclaimed by classic writers to be the finest of its class in the world, could have been excavated to the very root of the foundations and deprived of its hundred columns, that tens of thousands of feet of its gracefully-carved marbles could have been burnt into lime or turned into new shapes and purposes, without a single record being left of the Titanic deed of destruction. Having briefly sketched the history of the place, the lecturer said that they had now learned that the building must have been gutted and wrecked in the great fire of 283 under the Emperor Carinus; and that it was hastily and disgracefully restored by the Emperor Diocletian in the clumsy style which characterised the patchwork of the Decadence. They had also learned that whatever parts were left standing of the Basilica at the end of the fourth century were pulled down in order that the materials might be used for building the church of St. Paul on the road to Ostia. The lecturer added, by way of consolation, that by tracing the lines of the foundation walls and by sorting the fragments of its architectural decorations they had been able to reconstruct the original design in plan as well as in elevation. A drawing of the restoration, the work of Signor Guiseppe Gatteschi, was shown on the screen. The Temple of Antoninus and Faustina, the next building reached, had been freed by their latest operations from its ignoble surroundings, and also restored.

The pavement of the Sacra Via which runs in front of the Pronaos is 4ft. higher than the original one, and there were five steps of the original stairs buried under the mediæval pavement. These steps have been uncovered and the Temple now appears in all the noble proportions of its original design. Discussing the Regia and its remains, the lecturer dealt particularly with two interesting relics of the building, namely, the circular structure in the inner hall, and the storepit or underground Tholos. The former is suggested to be the part of the sanctuary in which the spears of Mars were kept, while the storepit and the altar have been identified with the *Ops Consivia*, whose presence and worship in the Regia are attested by historians of early Rome.

Leaving the Regia, the lecturer next drew attention to the House of the Vestals. Entering the cloisters of the Vestals, the first monument met with is the pedestal of Claudia, the first and the only Princess of Vesta, who gave up her exalted position to embrace the Christian faith. Across the Nova Via one enters the newly-excavated colossal temple of the deified Roman emperors. Architects will find the temple a new and unexpected subject for study, so different is its plan and elevation from any known design of a Roman public building and so wonderful is its preservation. The building does not stand isolated on its own ground, but is connected with the Palace of Caligula and with the state stairs that descend to it down to the level of the Forum. It was already known from the discovery of similar stairs in the palace that the imperial architects, possibly the Emperors themselves, objected to steps, and that, whenever the plan of the building allowed it, they substituted for steps inclined planes, with an easy gradient of 6 or 7 in 100, interrupted by horizontal landings. The newly-discovered descent from the Palace of Caligula to the Temple of the Emperors is designed in the same way.

Lastly, the lecturer described the Imperial warehouse for Indian goods brought to light in the excavations. This establishment, officially styled the Horrea Piperatoria, was built by the Emperor Domitian, about 84 A.D., for the storage of the spices named and described by Pliny in the twelfth book of the natural history. The warehouses were wrecked and gutted in the fire which destroyed the whole quarter of the Sacra Via in 191 A.D., a few weeks before the death of Commodus. Considering the happy results of the excavations, the lecturer said their thanks were due to the Italian Administration of the Antiquities, and to their colleague, Commendatore Boni, for the scheme so cleverly planned and so skilfully carried through, and for their decision not to stop any more in the search at the level of the classic buildings of the Empire, but to reach wherever possible the lowest and deepest strata, contemporary or even anterior to the foundation of Rome. By following this scheme he felt confident they would ascertain the true origin of Rome, and the nationality and stage of civilisation of its original settlers.

A vote of thanks to Professor Lanciani was proposed by Mr. F. C. Penrose, and seconded by Sir Lawrence Alma-Tadema; Sir William Richmond, Professor Aitchison and Dr. Alexander Murray then spoke; after which the President put the vote, which was carried unanimously. The Professor returned thanks, and the meeting then terminated.

CLASSIC IRONWORK.

AT the meeting of the Birmingham Architectural Association held on Friday evening last, Mr. Thomas S. Elgood (of Elgood Brothers, Leicester) read a paper on "Different Types of Classic Ironwork," a subject to which he has devoted many years of study.

Beginning with Italy, he pointed out that though that country was the very home of the Renaissance, though the Italians produced such marvellous results in every other branch of art, yet they did not evolve any great and characteristic Renaissance style of ironwork. Rather, the different cities seemed to develop little styles of their own, that of Venice being very distinct from many of the others. (This was illustrated by sketches made in Pisa, Florence, Venice, and Verona.) The Germans, too, though they were so great in smithwork and so readily adopted Renaissance qualities in their armour, locks, and other articles, did not freely assimilate Classic ideas in their architectural ironwork, but wasted their ingenuity and strength upon the well-known puzzle ironwork, the flatness and insipidity of which is fortunately relieved in many cases by really good foliated and floriated crestings. When they took up the Rococo they overdid it in the most painful manner. The French, in the times of Louis XIII. and Louis XIV., produced that most remarkable and most Classic style known as the Baroque or Jesuit style, and embellished their buildings with gates, balconies, and balustrades designed in the best spirit of the Renaissance and executed with unsurpassed skill. (This was illustrated by many examples from Paris, Versailles, and Rouen.) Of the Rococo which followed, the lecturer had little to say, and few examples to show. Later, again, in the time of Louis XVI. and the Empire, a more simple and Classic taste returned, but not the wonderful genius of the Baroque period. In Spain at the end of the fifteenth and on through the sixteenth century the Plateresque (or silversmiths') style of ironwork grew up, giving to posterity all those wonderful screens or *rejas* in the great cathedrals at Toledo, Cuenca, and Palencia; also that wonderful gem—the pulpit at Avila, and balustrades like that at Burgo. The illustrations of these examples were taken from Mr. A. N. Prentice's book and were supplemented by a fine photograph of the exquisite Spanish Gates in Chester Cathedral, which are of the very best period. In England the so-called Queen Anne style of ironwork was developed. Small beginnings are noticeable as far back as Elizabeth; the most remarkable developments took place during the reign of William and Mary, particularly under Wren, who employed at Hampton Court and at St. Paul's Cathedral Jean Tijou as designer and Huntingdon Shaw as smith. Some of the best illustrations to the paper were from these two buildings, Mr. Elgood's favourite being the gates leading into the choir aisles at St. Paul's, which he spoke of as one of the very finest examples of the architectural treatment of wrought iron. Under Anne and the early Georges the style became more simple, and examples are too numerous to catalogue. They may be studied to advantage all about London, in the Cathedral cities, and at the Universities (particularly Cambridge), as well as in the gates to many country parks. Thus we have three great styles:—The French Baroque, the Spanish Plateresque, the English Queen Anne; and three lesser ones:—The Italian, the Rococo, the Empire; and of them all the most adaptable and most economic is the English.

Law Cases.

Embezzling an Architect's Money.—At the Tunbridge Wells Police Court on November 5th Nicholas Strange, an accountant, was charged with having embezzled sums of money amounting to over £300, belonging to W. B. Hughes, an architect and surveyor. From the evidence it appeared that the prisoner, who was engaged by Mr. Hughes as confidential clerk and auditor, was entrusted with large sums of money to bank, a part of which he occasionally appropriated to his own use. It was further alleged that he altered the office books and repeated the falsifications at the audit which he himself conducted at the end of each half-year. The prosecuting solicitor, Mr. W. C. Cripps, stated that the total defalcations appeared to be over £900, and more discrepancies were being discovered as the examination of the books proceeded. The prisoner was committed for trial at the assizes.

Apportioned Costs of Paving Improvements — The case of *Cawston* v. *Bromley Urban District Council* was heard in the Queen's Bench Division of the High Court of Justice on Thursday last. It was an award stated by agreement in the form of a special case. The Bromley District Council on February 13th, 1897, gave notice under the Public Health Act, 1875, to Mr. Cawston, of Bromley Hill, to sewer, pave, &c., a portion of Highland Road, Bromley. The notice not having been complied with the Council executed the works, the expense of which was certified by their surveyor at £717 11s. 9d. The surveyor declared that sum chargeable against the frontagers, and apportioned £372 12s 4d. as being the proportion payable by Mr. Cawston in respect of the frontages owned by him. Mr. Cawston disputed the apportionment, and in pursance of sections 150 and 257 of the Public Health Act, 1875, appointed an arbitrator. The Council also appointed an arbitrator. The arbitrators, having differed, appointed an umpire, who, by agreement, stated his award in the form of this special case. At the hearing before the umpire it was contended on behalf of Mr. Cawston that he was entitled to dispute the right of the District Council or their surveyor to charge part of the amount which was paid for work executed to the road on the ground that such amount related to a sewer already vested in the District Council. The Lord Chief Justice, in giving judgment, said that in his opinion this was an attempt to induce the Court to decide a question which had already been decided in the Court of Appeal ever since *Bayley* v. *Wilkinson* (16 C.B., N S, 161), and through a long series of cases ending with the Sandgate case (1892. 1 Q.B., 831) and the Folkestone case. In his opinion the surveyor's certificate for the purposes of the arbitration was binding upon the umpire as to the total amount. Mr. Justice Kennedy concurred.

Liability of Architect When Ordering Goods.—Mr. Justice Channell, sitting with a common jury in the Queen's Bench Division, recently heard the case of *Main* v. *Cotman*, which was an action to recover £38 odd, the price of goods supplied and work done. Plaintiffs' counsel said his clients were engineers and iron-founders, and defendant was an architect practising at Ipswich. The claim against him might be divided into three parts: first, the supply of a circulating boiler; secondly, repairing and re-fitting a triple gas-range; and thirdly, taking out an exhaust pipe and fitting it in another place. The defendant denied that the goods were sold to him, and denied that the work was done at his request, or for him at all. The chief question was whether the defendant ordered the goods, and whether he was liable. There was no dispute about the work being done, or about the prices charged being fair and reasonable. The order on which the action was based was given on Feb. 28th, 1898. Shortly before that date the defendant was acting as architect of the Crown and Anchor Hotel, Ipswich, and ordered a great number of articles and goods for the house. The plaintiffs sent in their bill to the defendant, who, very much to their surprise, took no notice of it. After repeated applications he said he was not liable. Still further correspondence took place, and the defendant suggested that a Mr. Quilter, who was the tenant of the hotel, was the person liable, and suggested that the plaintiffs should write to him. A letter was accordingly written to Quilter, who, however, forwarded it to the defendant. He denied that he had anything whatever to do with it, or that he was responsible in any way. Defendant's counsel said it was the duty of architects to give these orders, and, if every architect who did his duty in the ordinary way was to be called upon when a job was finished to put his hands in his pockets and pay all these people, and then to bring an action against his principal, the position of an architect would be a very precarious one. The action ought to have been brought against Mr. Quilter, who had been using the boiler for 2½ years. The jury found for defendant. Judgment accordingly, with costs.

Surveying and Sanitary Notes.

The Local Government Board Requirements for Sewage Disposal Schemes have been arranged in table form on a single sheet by Messrs. The Adams' Patent Sewage Lift Company, of York. This will be found most handy for the use of engineers, surveyors, &c.

London Sanitary Administration.—For the first time since the passing of the Metropolis Local Management Act of 1855 it is now proposed to enact drainage by-laws which that Act empowers the London County Council to adopt subject to the confirmation of the Local Government Board. The proposed by-laws have been forwarded to the Board, and Mr. Mark H. Judge has written to the Board pointing out that after a delay of nearly half a century "an opportunity should be given to the new Metropolitan Borough Councils to carefully consider these proposed new by-laws before the Local Government Board give them the force of law." The Public Health Committee report that they are "advised that the by-laws will be binding upon all parties, and that it will be the duty of the Borough Councils to see that they are observed."

Imperial Institute Road.—In February last the Building Act Committee of the London County Council received a letter from Her Majesty's Office of Works drawing attention to the removal of the University of London to South Kensington, and stating that the Senate considered it desirable that the name of the road in which the University buildings were situated should be altered from Imperial Institute Road to University Road, an opinion in which the Office of Works and the Treasury concurred. Apart from other considerations it appeared to the committee inexpedient to change the name to University Road, inasmuch as that name was already in use in London, and by their direction a communication to that effect was sent to the Office of Works. Letters were, however, subsequently received from the University of London stating that the Senate had adopted the name University Avenue, and that they desired that the Council would rename the road accordingly. After ascertaining that the London University was permanently located in the Imperial Institute Buildings, the Committee issued the notices required by the London Building Act, 1894, of the proposal to change the name, intimating at the same time that the Council was prepared to consider any objections. The attention of the Imperial Institute was specially called to the matter, and a communication has been received from the governing body strongly objecting to the suggested alteration, pointing out, amongst other considerations, that the expense of constructing the road was borne out of the funds of the Institute in accordance with the conditions upon which the site was granted for the erection of the building. Having carefully considered the matter, the Building Act Committee now state that they are not prepared to advise the Council to make any alteration in the name of Imperial Institute Road, and they have caused the University of London and the Imperial Institute authorities to be informed of their decision.

Professional Practice.

Grayshott.—A new church was consecrated recently. The building, which has been erected from designs by Messrs. I'Anson and Sons, architects, is in the Early English style, and consists of a nave, about 70ft. long, two aisles, and chancel with a tower which is not yet complete. The church is faced inside with local stone, and outside with Bargate stone, and Bath stone dressings, while the quoins are of Headley stone. Seating accommodation is provided for about 300, but this number was greatly exceeded at the consecration service. The seats are of pitch pine, the flooring is of wood blocks, and the altar, pulpit, and lectern are of oak; some of it, which is very old, having been taken from some farm buildings in the neighbourhood. The roof is covered with red tiles. The church has not been built, as is usual, by contract, but it has all been done locally under the superintendence of Mr. Foster, who has acted as clerk of the works, or general manager, under the direction of Mr. I'Anson, who, it should be mentioned, has given his services as architect. The total cost, apart from gifts, has been between £7,000 and £8 000.

Wycombe.—A new Church of St. John is to be erected in the Desborough Road. The architect is Mr. W. D. Caröe, of Whitehall Place, London, S.W. The limitations of the site lend themselves to the type of plan by which the whole congregation, occupying the nave, are under a single span. The seating accommodation of the church will be 741. There will be a broad nave and narrow aisles, the latter being merely passages. It is planned with a side chapel, choir and sanctuary organ chamber, &c. The morning or side chapel forms a south transept, from which the main altar is visible, and is thus serviceable for general as well as for special offices. It has been pointed out that it is essential that the building, if possible, should not abut the roadway. A narrow pathway has, therefore, been allowed on the south or West End Road side of it. A sanctuary will be low and side-lighted. The east end will be occupied by a reredos. The east window is in a clerestory over the sanctuary arch, and the whole of it will be visible from the west end of the nave. The floor will be raised to the level of the West End Road. By this arrangement, it is possible to place the vestries beneath the chancel, and thus secure the advantage of avoiding the covering of the restricted area of the site available with extended buildings. There are to be five entrances directly to the church, and one to the vestries. The nave is to be covered by an open timber roof of substantial construction, and the chancel by a barrel roof, which will materially assist the acoustics of the place. It is proposed to build of brick, and the amount of stone employed, except in the upper stages of the tower, is reduced to a minimum. While the tower itself does not come into the immediate scope of the present scheme, it appears on the design. The architect, on account of the oblong form of the church, has adopted the "saddle-back" covering, the height of the tower, by the way, being the same as that of the Parish Church. Until the upper stages of the tower are erected, the nave roof will be continued over it as a covering, and the whole will be complete in itself. The heating chamber is to be placed beneath the morning chapel sanctuary, and is thus very convenient for the discharge of fuel direct from West End Road. The detail of the style of the church is formed upon the developed "second pointed" work of the early part of the 14th century, a type of which Buckinghamshire boasts some exquisite examples. The cost of the whole fabric, exclusive of the tower, works out, at present prices, at £9,900, of which about £900 has to be spent before reaching the floor level; but it is only contemplated to complete a portion of the church at first. The first portion will cost £3,850, including £450 for temporary work, or if the sanctuary and the morning chapel be erected, £320 more. The cost of the tower will be about £2,000

Partick, Glasgow.—A new school has been erected for the Govan Parish School Board. The site on which the school is built consists of 7,056 square yards, and was purchased for 10s. per sq. yd. The school buildings, which were estimated to cost £18,940, occupy practically the centre of a square, and are bounded by four streets. The front playground is set off with rows of trees encircled with neat iron railings. The main building, which is three storeys in height, with accomodation for 1,348 scholars, is built of Locharbriggs redstone. The basement floor of the school contains laundry, manual instruction workshop, heating ducts, chambers, &c. The janitor's house is on the ground-floor level, and on this level the school proper commences, with separate entrances for boys, girls, and infants, where, occupying the central portion of the buildings, there is a large central hall. This hall is open through the entire height of the building, and is spanned, on the upper floor, by a bound roof, filled in with glass for lighting. There are also, on each floor, open balconies, supported by ornamental cantilevers, round the four sides of the hall. These balconies give access from the various floors to the classrooms of the several departments. At either end of the hall are spacious open staircases, and on the half-landings and main landings the cloak-rooms and teachers' rooms are placed alternately. Electric bells and speaking tubes from the central hall and headmaster's room communicate with the various floors; these special features forming a useful adjunct to the satisfactory working of the school. The various classrooms have been supplied with furniture and appliances of the best type. The heating and ventilating arrangements were designed and carried out by Mr. Preston, the Board's Master of Works, and are on the propulsion system. The temperature is raised by propelling fresh air, filtered through a specially-prepared hair screen, over steam-heated coils placed in the shafts leading to the several classrooms. This arrangement allows of each room to be independently heated. A large air propeller is driven by a gas-engine, which also drives grindstone, &c., for manual instruction workshop. In the laundry, which is fitted for sixteen girls, the boiling and drying are done by steam. The buildings, which were begun in August, 1898, are from designs by Mr. Andrew Balfour, I.A., architect, 110 Mains Street, Glasgow; the measurers being Messrs. Smellie, Taylor, and Browne, 167 St. Vincent Street, Glasgow; and have been erected under the superintendence of Mr. Samuel Preston, master of works to the Board. Mr. Rodie acted as clerk of works.

MANCHESTER ARCHITECTURE.

A CRITICISM OF RECENT BUILDINGS.

WE take the liberty of reprinting from the "Manchester Guardian" the following excellent criticism of buildings recently erected in that city:—

In any town where smoke and grime take as fast and lasting hold of stone as they do in Manchester, a building material should be welcome that can even partially defy such defacement. The shimmer of marble or granite in our climate, and with our surroundings, is apt to be inartistic in its effect—much as a jewelled ring is upon a coarse and dirty hand. Terra-cotta and the better kinds of brick are less open to this objection; but as used in Manchester, with very few exceptions, terra-cotta buildings are designed as for stone, and as if just coloured on the drawings or described in the specification as terra-cotta. That is making a bad use of a good material. Every building should surely be designed in detail to suit the special characteristics of the materials employed.

The new building called the Deansgate Arcade is, in the general treatment of the façades—especially the easterly one—and in detail, better adapted to terra-cotta than most others in Manchester. The design is not of the "wedding cake" description, and it suits the material in most respects well. This building is alone enough to show that there is no need in the use of terra-cotta to do violence to any artistic rule or sense. The elevations are dignified and suited to the purpose of the building. But even here there is one grave artistic fault, for which doubtless the architect would say that his clients are responsible. There is a vast mass of building over the wide shop fronts with no visible adequate support. This is an old problem yet to be satisfactorily solved. A minor point is that the terra-cotta blocks are in many cases too large for consistent terra-cotta treatment. Still, this is on the whole a satisfactory town building such as we are glad to see.

There is, unfortunately (with, of course, a notable exception), little besides in Deansgate to notice with approval. The Religious Institute and offices of the District Provident and Charity Organisation Society on the other side of Deansgate, next to the School Board offices, fall sadly short in many ways. The general treatment is confused and incoherent—it cannot be called design. The conditions, such as the varied uses and different heights required, lend themselves to a picturesque grouping and outline, of which, unfortunately, there is no trace in the building as we see it. Terra-cotta, too, is used without any serious attempt to give it the treatment for which the nature of the material calls. Artistically and architecturally it is impossible not to feel that a good opportunity—almost a great one—has been thrown away.

There is a striking façade in Fountain Street—the offices of the Guardian Society for the Protection of Trade. The ground floor, lofty enough to admit light duly in a narrow thoroughfare, is all of grey granite, which, by the way, would have been better if all polished or all unpolished. As it is, it suggests the idea of a face usually shaved of which only a part has to-day felt the razor. The first-floor windows are treated effectively and freshly, and the upper windows, forming a sort of continuous arcade, are excellent. Moreover, there is an absence of the so-called and miscalled ornament that disfigures so many of our more recent buildings.

A new building that has attracted a good deal of attention is the new warehouse in Piccadilly of Messrs. Horrocks, Crewdson and Co., and it deserves commendation for a certain freshness of design—a something that we have not seen here before. One is sorry that in a case where the architect has obviously had a pretty free hand as to expense there should be any serious faults. For such an important building there ought to be a befittingly important entrance. Yet one has almost to look for the door, and when found it is seen to be only a round arched opening, poor, if not actually mean, in design. The quasi bell-cot, too, on the front gable makes one wonder whether the architect had, when he got up there, come to the end of his resources; and no trouble seems to have been taken with the chimneys. It is remarkable that while our forbears, as a rule, made their chimneys a strong point in every design, knowing how a good chimney will redeem a plain or even a poor design, we of the present generation, or most of us, miss this point entirely. There seem to be plenty of ledges on which dust and dirt will lodge, and the rain, instead of helping to clean the elevations, will, it is to be feared, wash down the dirt from these projections and so cause much disfigurement.

Dignity and stateliness are one thing. Some architects in aiming at these only arrive at stiffness, coldness and hardness. Quite another thing is the cast-iron style. We feel grateful to Mr. Waterhouse for the promise he gives us, in the Whitworth Hall of Owens College, of something with less of cast-iron design in it than is his wont. The design is dignified, and some of the parts in detail—as, for example, the main entrance—are graceful and impressive. But the effect would have been much improved had the five front bays had some slight alternative treatment, both in the windows and in the panelling. It would take nothing from the dignity, but would take much from the stiffness. Witness that most dignified cathedral at Chartres—the skilful and ingenious alternation and the gain in artistic effect and interest. It is to be wished that the roof covering might be of reddish-brown or even purplish tiles. The light red tiles do not seem to have weight enough for such buildings. Also the gimcrack ridge crest would be better absent. The new Physical Laboratory (see BUILDERS' JOURNAL for July 11th last) excites regret that it should be so severely simple in its treatment. The details, though refined, lack due boldness, and thus a lofty and what should be an imposing building does not possess the impressiveness which its size and evident cost should give it. But it teaches one important lesson—the value of red brick. What a difference it would have made if all the dirty white brick buildings which make up the westerly part of the Owens College group had been of such red brick as the Physical Laboratory, and relieved, like it, with stone.

For a moment compare other buildings, modern and ancient. Whatever may be the merits or demerits of G. E. Street's London Law Courts, no one can deny that his mixture of red brick with stone is extremely clever, and is an absolute success. In York and in many parts of Yorkshire, see how perfectly effective is the way in which red brick and grey stone are intermingled, especially effective where there are also the rich red-brown tiled roofs. What a difference, too, in artistic effect would it have made to the Physical Laboratory had it been covered with brown or even purplish tiles, instead of very red ones on a building that was already quite red enough. The architect of the Physical Laboratory might have crowned his building with good chimneys. There was such a chance; why miss it? The chimneys are worse than poor; they are needlessly and objectionably ugly.

In the Women's Hospital in Oxford Street there is a far more consistent and reasonable use of terra-cotta than in the great insurance building nearly opposite; that is, a treatment more suited to the material, and much less suggestive of a stone design carried out in the humbler material. But (there is always a "but") one is very sorry to see the canal front so meanly treated—even worse than the west front of the Manchester Grammar School, though that is saying a good deal. In Manchester and Salford there are and have been many opportunities of giving due dignity to a river or canal frontage, which is sometimes better seen even than the street front; but few here seem to see that it is an opportunity to be used. At York, by the Ouse, there is a faint idea expressed in places that something ought to be done. We need not go to Venice for precedent. At Ghent and Bruges there is less magnificence but still very delightful treatment of water-side buildings of almost every conceivable kind. The great warehouse of the Tootal Broadhurst Lee Company, in Oxford Street, has on its southern side, next the canal, paid the courtesy to the passing public of a carefully designed front. There is another case in Messrs. J. Woolley and Sons' great building, seen as one approaches Exchange Station, where the conspicuous riverside has been architecturally treated—or rather a sample bit of the side; for, strange to say, the properly designed part stops a few feet from the corner, and the rest of the river front is little better than a wall with holes where wanted for light.

Of new public fountains in Manchester, that in Albert Square, simple as it is, is of really good artistic design; no architect, however eminent, need be ashamed of it. Another, though it takes us in spirit to that of Trinity College, Cambridge, is but a parody of the ancient fountain; it is poor and even mean in many of the details, and the water issues in the centre from a paltry earthenware vessel.

Liverpool Architectural Society.—The second ordinary meeting, fifty-third session, of this society was held last week, Professor Simpson presiding. Mr. Sebastian Pugin Powell was elected a Fellow of the society, Messrs. Frederick G. Barker and Matthew Honan were elected associates, and Messrs. Elliott Irvine Bingham, E. W. Evans, J. Anstice Harrison, T. Alwyn Lloyd, Edgar Quiggin student members. After the business of the meeting had been transacted, Mr. Halsey Ricardo read a paper on "The Revival of Gothic Architecture," which is printed in full in this issue.

THE CONSTRUCTION OF A ROOF.*

By GEORGE H. JONES.

IN our climate the roof of a building is of the first importance, for however perfect the structure, however elaborate the conveniencies and fittings, however artistic the decorations and scientific the sanitary arrangements, unless the roof is well constructed and watertight all the labour is in vain.

The subject of roofing generally (embracing as it does construction and materials) is too large to be dealt with in a short lecture like this, but a few notes will probably be of use.

Most of you have studied the construction of stone roofs and vaulting under that able instructor Laurence Harvey, at the City and Guilds of London Institute. Stone roofing and vaulting will always have a fascination for the members of this college, and rightly so. But I would urge upon those of our younger members, who have an ambition to become general foremen or clerks of works, the importance of studying the roofs of the carpenter. The iron roofs of our railway termini, markets, and other public buildings are also well worth the consideration and study of our members, though these structures are, as a rule, the work of the engineer rather than of the architect.

The chief use of a roof is, of course, to protect the inmates of the building from the extremes of temperature, from wind and rain. It must be designed and constructed in such a manner that it is a support to the walls that carry it, and unless it fulfils these requirements it cannot be considered a satisfactory, much less a perfect, roof. In the designing of a roof there are many things to be considered—the span or width between the walls, the height of the ridge, the weight of the covering (whether lead, tiles, or slates), and the relative strengths of the various timbers. If it is a high-pitched roof it is generally trussed on the king-post principle, or if low-pitched, on the queen-post principle, or sometimes by a combination of both. Though the problem of designing does not devolve upon the clerk of works or the general foreman, it is essentia l.hat they should understand the principles of construction and proper framing.

The simplest form of roof suitable to our climate is what is known as the lean-to roof, that is, a roof that slopes only one way. This was probably the earliest form of roof constructed in this country. Then would follow the ridged roof, or the roof which slopes two ways, with the end walls, called gables, carried up in brickwork or masonry. After this would follow the hipped roofs, sloping three or four ways. It would soon be discovered in the roof sloping both ways that the feet of the rafters had a tendency to spread and force out the walls. The next step was to tie the feet of the rafters together, and thus arose the tie-beam. The sagging of the tie-beams over large spans would next attract attention, and the remedy was found by suspending it from the ridge. Here then was the truss, the king-post truss. The queen-post truss is but the extension of the king-post truss. The latter is probably the earliest, as it is the simplest, form of roof-truss. The king-post holds up the middle of the tie-beam, and the struts support the middle of the rafter: they should be at right angles to the back of the rafter and should be tenoned and shouldered on the king-post. Nowadays, in roof framing, the tie-beam is frequently dispensed with, being replaced by a timber at a higher level than the feet of the rafters, sometimes as high as half the distance to the ridge; this is called a collar beam, and when it is fixed at a high level it is framed to the feet of the rafters by braces. Any piece of timber in a truss on which the stress or strain is in the extension of its fibres is, and may be called, a tie (sometimes brace). When the strain is in compression of its fibres it is a strut. Thus a king- or queen-post is a tie and not a strut.

The cost of trussing every pair of rafters would soon lead to longitudinal framing, and so came the purlin. The purlin is usually laid on the back of the principal rafter, sometimes at right angles and supported simply by a splay block spiked on the rafter, and sometimes fixed vertically and notched down over the rafter. When the principals are far apart, the purlin is sometimes strutted from the tie-beam, or from the sides of the principal rafter in open roofs; and these are called wind braces by some. They are of very little use when fixed to the side of the rafter, but some persons admire them in open roofs. If a roof is placed on inner and outer wall plates, these should always be framed together by cross-pieces halved and dovetailed, and not morticed and tenoned as I once saw done. Roofing is, in my opinion, the perfection of the carpenter's art; and the open roofs of our churches are, in many cases, even more beautiful than stone groining. To those of you who do not agree with me, I recommend a visit to Westminster Hall.

Thus we have seen the truss or principal rafters carry the purlins and ridge, the common rafters being fixed on the purlins, ridge, and wall plate. There is a German method of dispensing with the common rafters: this consists in fixing purlins at intervals from plate to ridge and then boarding them over to carry the slates or battens. I should think a roof like this would be less effective against wind pressure than one built in our usual way, though it would probably be less expensive to construct.

When a roof is described as being framed in rough fir or oak it is meant that the timber is used as it comes from the saw; when it is to be planed it is described as wrought: the framing is the same in both cases. When the soffit of a common rafter comes below the back of the purlin it should be caulked into the sides of the latter, but nothing must be taken off the back of the purlin. In some cases it is advisable to double caulk, in order to save the sectional area of the purlin as much as possible. I find there is a tendency to forget the caulking in rough framing: this, however, is important, and must be insisted on; especially when the purlin is at right angles to the rafter. In joggling in braces, &c., the shoulder should always be at right angles to the thrust, and if the joggle is long it should be twice shouldered for the same reason given above; in morticing never cut away more than is necessary. In fixing the bolts in a truss the bolt should in almost every case be fixed at right angles to the bi-section of the inside angle of the two timbers to be bolted together.

An excellent roof which I saw fixed on a building is constructed on the king-post principle with the addition of a hammer beam; the need for this beam being obvious in this particular case. The main principals are constructed with rafters, collars, braces, ashlars and hammer beams, with iron tie-rod and king-bolt. The feet of the rafters are, with the ends of the hammer beams, framed into a cast-iron shoe, through which the tie-rod passes; the rafters are framed together in a cast-iron head, and the king-bolt passes through and suspends the tie-rod. There is a seat or collar cast on each side of this head to carry the ridge, which is bolted through it on each side. From the hammer-beam there is a curved strut framed into the wall-post and beam resting on a stone corbel. The intermediate principals have no tie-rod or king-bolt (these are replaced by a king-post), and the collar is braced to the rafters; the iron head and shoe remain. The collar is strengthened by straps to king-post and rafters. In this truss there is a short tie-bolt passing through the hammer-beam and holding in the longitudinal beam. This latter runs the whole length of the building and the hammer-beams of all rafters, principal and common, are framed into it.

The purlins are housed and tenoned into the sides of the principal rafters. This is necessary, because backs of all rafters lie in one plane. The common rafters are all framed in trusses and caulked into purlins and notched over ridge and plate. The framing pieces of the plates are so arranged that every alternate rafter shoes on top, the others being bird's-mouthed to the plate. The reason for this is obvious after my previous remarks about purlins. The common rafter truss consists of rafters, collar braces, ashlars, and hammer beams, and alternate long cross-braces, with a short collar between. In framing the plates the principal hammer beams are notched down over the inner plate, while the outer plate passes by almost clear of the cast-iron shoe. The hammer beams to common rafters lie on the top of the plates. The roof is also counter-rafted diagonally, the slate battens being nailed to these rafters.

* Paper read before the College of Masons at the Royal Architectural Museum, Westminster, on October 23rd, 1900.

Engineering Notes.

Municipal Tramways in Kent.—The authorities of the districts from Plumstead to Dartford have agreed to ask for powers for an electric tramway. The proposed line will run from the existing metropolitan system at Plumstead through East Wickham, Welling, Bexley Heath, Crayford, and Dartford. Both the Dartford and Bexley urban authorities have the electric supply in their own hands.

New Pier at Bexhill-on-Sea.—The Urban District Council, having definitely decided to apply during the ensuing session of Parliament for powers to construct a promenade pier, have instructed Messrs. Mayoh and Haley, civil engineers, of Amberley House, Norfolk Street, London, W.C., who have already submitted their report and are now engaged on the necessary plans for the Board of Trade,

Electricity on German Farms.—At Coburg and neighbouring parts of Germany considerable attention is being paid to electrical appliances that can be used on the farm. Near Ochsenfurt, in Bavaria, a company has been organised for the establishment of an electrical system for use on their farms and in villages. The power is to be generated by steam and water, and the current to be distributed from a central station to the places at which it is wanted. Sub-stations are to be established at given points, with the necessary apparatus for connecting with the farm or other machinery, and also for lighting purposes in the houses, offices, roads, and village streets.

The Gas-meter at the Rotherhithe Baths.—At last Wednesday's meeting of the Rotherhithe Vestry the Baths and Washhouses Committee submitted a report in reference to the gas-meter at the baths, which, it is stated, for 18 years has registered only one-tenth of the quantity of gas consumed, owing to the dial indicating hundreds for thousands of cubic feet. Recently the South Metropolitan Gas Company sent in a bill for £2,947 for the arrears. Mr. Macmorran, Q.C., who had been consulted, could not advise the Vestry to pay the claim, except in obedience to a *mandamus* or order of a competent Court. The committee recommended that the clerk be instructed to inform the company that the Vestry had no power to levy a restrospective rate to meet the claim, and, therefore, they could not admit any liability in the matter. The recommendation was unanimously adopted.

The Institution of Electrical Engineers held its inaugural meeting of the new session on Thursday last, Professor Perry, the president, in the chair. Asking the question whether electrical engineering was to remain a profession or was to become a trade, the Professor urged the importance of electrical engineers being well acquainted with theory and the simple mathematics by means of which theory was made available. If they neglected these subjects they would probably find themselves left behind, for electrical engineering was in its youth and was growing rapidly. We in England, he maintained, knew too little theory, and much of the evil we suffered from was due to the average young men being pitchforked into works, where they got no instruction, as soon as they left school. Mathematics ought to be the natural language of the electrical engineer whereas at present it was a foreign tongue.

Leadless Glazed Ware.—Messrs. Mortlock, of Oxford Street, W., have arranged to show a large number of specimens of ware coated with leadless glaze, sent from the Royal Worcester Works.

Property and Land Sales.

To White Lead Manufacturers and similar Trades.—Ready equipped premises.—WILLESDEN JUNCTION.—Freehold Manufacturing Premises, situate on the Grand Junction Canal, and near a railway siding.

WEATHERALL and GREEN will SELL by AUCTION, at the MART, City, on MONDAY, NOVEMBER 26, at TWO o'clock, the valuable FREEHOLD MANUFACTURING PREMISES known as Hythe Works, Hythe Road, Willesden Junction, possessing a frontage to Hythe Road of about 98ft. 6in., and to the Canal of about 105ft., covering over half an acre, and comprising manager's house with office accommodation and a substantially constructed and well-lighted factory, with workshops and store-rooms, equipped with plant and machinery for the manufacture of white lead; the premises are in capital repair, and from the advantages of position and facilities afforded for delivery and despatch of goods readily lend themselves for use for almost any trade.

Particulars and plans of WALTER E. BROOK, Esq., 14 South Square, Gray's Inn, solicitor; at the Mart; and of the Auctioneers, 22 Chancery Lane, W.C.

New Companies.

Vulcan Incandescent Light Syndicate, Limited.

This company was registered on October 26th with a capital of £10,000 in £1 shares to manufacture and deal in incandescent-light mantles, burners, glassware, lamps, accessories, &c. Registered office: 34 Faulkner Street, Manchester.

Electrical Trades Supply, Limited.

This company was registered on October 30th with a capital of £5,000 in £1 shares to carry on at Birmingham or elsewhere the business of electric, gas, water, and mechanical appliance manufacturers, motor-car, cycle, vehicle, dynamo, motor, telephone, bell, electrolier, accumulator, lamp, and fittings manufacturers, &c.

Yorkshire Electric Power Syndicate, Limited.

This company was registered on October 25th with a capital of £10,000 in £10 shares to carry on in the West Riding of Yorkshire, south of the River Wharfe, or elsewhere, the business of an electric power supply company in all its branches. The first directors (to number not less than three nor more than twelve) are to be appointed by the subscribers. Registered office: 7 St. Helen's Place, E.C.

Oaklands Cottage Company, Limited.

This company was registered on October 29th with a capital of £1,000 in £10 shares to acquire or erect and maintain dwelling-houses for the labouring classes or otherwise, and to carry on the business of builders, contractors for public and other works, freehold, leasehold, and copyhold property owners, financiers, &c. Registered office: Ivy Cottage, Hill Street, Aberaman, Aberdare, Glamorganshire.

Graig Forest Colliery Company, Limited.

This company was registered on October 29th with a capital of £6,000 in £5 shares to acquire mines and property, to search for, get, raise, make merchantable, sell, and deal in coal, cannel, ironstone, shale, fireclay brick earth, and other materials, metals, and substances. The first directors (to number not less than three nor more than seven) are J. Dovell, W. A. B. White, and J. F. Beresford.

Unlimited Fuel Company, Limited.

This company was registered on October 23rd with a capital of £1,200 in £1 shares to acquire certain patents relating to the manufacture of fuel, to adopt an agreement with Paul D'Humy and George A. Watson, and to carry on the business of dealers in coal, iron, ironstone, brick-earth, and other minerals and metals, &c. The first directors (to number not less than two nor more than five) are G. A. Watson and P. D'Humy.

Talbot Continuous Steel Process, Limited.

This company was registered on October 19th with a capital of £300,000 in £1 shares to adopt an agreement with H. Le N. Foster to acquire certain exclusive or non-exclusive rights to deal in or with any secret or other inventions in relation to the manufacture and treatment of steel, iron, &c., or in relation to any mechanical appliances used in or in connection with the same. The first directors (of whom there shall be not less than three nor more than twelve) are to be elected by the signatories, S. C. Masters, A. C. Stock F. W. Newell, F. J. Burrows, P. Binks, W. J. A. Drake and R. Spalding.

Ware Brickfields, Limited.

This company was registered on October 30th with a capital of £20,000 in £5 shares to acquire any buildings and property in Hertfordshire, or elsewhere, and to carry on the business of brick, tile, and pipe manufacturers, dealers in brick, earth, stone, chalk, sand, lime, gravel, timber, hardware, and building materials, &c. The first directors (to number not less than three nor more than five) are J. Smart, W. H. Norris, and W. C. H. Burne.

Brabazon House, Limited.

This company was registered on October 31st with a capital of £12,000 in £50 shares to acquire the benefit and obligations of an agreement between Lady Kelvin, Amy Tate and Evelyn Hopkinson, and the Ecclesiastical Commissioners, for a building lease of a site in Moreton Street, Westminster, and to erect, equip, and maintain boarding-houses, lodging-houses, chambers, &c. The first directors (to number not less than three nor more than seven) are Mrs. E. Hopkinson, Miss J. L. Lindsay, Colonel H. Locock, C.B., and W. H. Upjohn, Q.C.

CONTRACTS OPEN.

DARLINGTON CORPORATION WATERWORKS.

The Corporation of Darlington are prepared to receive TENDERS for the CONSTRUCTION of an additional ENGINE-HOUSE and BOILER-HOUSE and other Works at their Tees Cottage Pumping Station.

Drawings may be inspected, and specifications and forms of Tender, with schedules of quantities, may be obtained on payment of Two Guineas (returnable if a bonâ-fide Tender be made) at the Borough Surveyor's Office, Town Hall, Darlington, and at the Office of Messrs. T. & C. HAWKSLEY, Civil Engineers, 30 Great George Street, Westminster.

Tenders, endorsed "Tender for Engine-house, &c." and addressed to the Chairman of the Waterworks Committee, to be delivered at my Office, Houndgate, Darlington, on or before THURSDAY, the 22nd NOVEMBER, 1900.

The Corporation do not bind themselves to accept the lowest or any Tender.

By order,
HY. G. STEAVENSON,
Town Clerk.

Darlington, October, 1900.

TO BUILDERS AND CONTRACTORS.

The Guardians of the Poor of the Parish of Paddington invite TENDERS for the ERECTION of BOARD ROOM and OFFICES in Harrow Road, W., pursuant to plans and specification to be seen at the offices of the Architect, Mr. F. J. SMITH, F.R.I.B.A., Parliament Mansions, Victoria Street, S.W., between the hours of TEN and FIVE, where all necessary information can be obtained, as also form of Tender, upon which alone proposals will be received.

Bills of quantities may also be obtained at the offices of the said Architect, on payment of a deposit of £10 10s. which will be returned on the receipt of a bonâ-fide Tender for the work.

Sealed Tenders must be delivered at the offices of the said Guardians at the Workhouse, Harrow Road, W., before FIVE o'clock on TUESDAY, the 4th prox.

The Guardians do not pledge themselves to accept the lowest or any Tender.

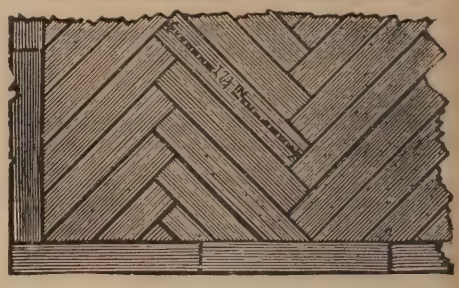
By order,
HENRY F. AVELING,
Clerk to the Board of Guardians.

No. 289 Harrow Road, W.
November 1900.

BOROUGH of SOUTHEND-ON-SEA.
NEW TECHNICAL SCHOOLS.

The Corporation invite TENDERS for the ERECTION of NEW TECHNICAL SCHOOLS in London Road.

Applications for bills of quantities must be made to the undersigned on or before SATURDAY, the 17th NOVEMBER, accompanied by a deposit of £5, which will be returned on receipt of a bonâ-fide Tender.



Sealed Tenders, marked "Tender for Technical Schools," are to be delivered at the office of the undersigned on or before the 6th day of DECEMBER.

The Corporation will not be bound to accept the lowest or any Tender.

By order,
WILLIAM H. SNOW,
Town Clerk.

Southend-on-Sea.
November 1900.

An Architectural Causerie.

Billiard Room Design. The billiard room shown on this page is proposed to be built for Mr. Montague Goodall, at 8 Wedderburn Road, London, N.W., by extending a room on the first floor over the kitchen and scullery on the ground floor. The floor of the room is to be of oak in narrow widths, the panelling and pilasters, &c., on the wall in oak also, and the ceiling panels in fibrous plaster. A portion of the ceiling light will be constructed to slide in order to give ventilation through a skylight above. The lighting will be by means of electric light in beaten copper shades. Mr. A. H. Belcher is the architect. Our illustration is from a water-colour drawing exhibited at this year's Academy.

The Killing of the Proselyte. The General Public had been harshly criticised, it had been told that it possessed no artistic taste, was devoid of any sense of fitness, made itself an abject slave to novelty, and confounded bigness with majesty, profuseness with beauty. For years and years members of the profession, old and young alike, had told one another that the General Public was incorrigible, though they continued to discuss ways and means for its education. And at last the heart of the General Public was reached, it saw the depth of its ignorance, the bigotry of its ideas; it therefore became penitent, and in a humble spirit called on the Architect in order that it might learn the true principles of his art. The Architect was a sober and businesslike man, and, taking the general public by the hand, he said: "O! Public, know that the most beautiful buildings the world has ever seen, or will see, were those erected by the mighty men of Greece and Rome, whose temples vied with the sun in splendour, whose proportions entranced the eye and charmed the senses. They possessed harmony, simplicity and unity; what more could be desired? These, therefore, are our models, which we see by the reflected light of a Renaissance." The General Public already possessed a hazy idea of what the Greeks said and did, though it had never read Homer, and was not quite clear as to how Hannibal occupied his time. But it followed the Architect, and presently they came to a large stone building with a number of semi-circular-headed windows. While it was realising the splendour of the building, another Architect came along and whispered certain things in its ear. Then it gazed at the building again, and really it did seem strange that windows should break through the pediments in that manner, and the ornaments on the cornice were not unlike pepper pots after all; in truth there was very little variety in it. "You never see those things in my building," said this second Architect. "The Gothic masterworkmen were perfect. It is they who should be our models. See how their resource shows itself on every stone, how the spires shoot up to the heavens on this side, how the lovely groins of the vaults join one with another. Note that no two capitals are alike; look at the springing arch, the flying buttress, the nestling column; see what variety. And all is truthful, all sincere. Here each mason has let fancy run free as the birds of the air, and the stone has become fashioned after the image of his soul. No slave was he, like the Greek mason, made to cut his stone in abject regularity, giving up his whole self to the devices of another." The General Public was obedient and believed what it was told. It had so long imbued the ideas and thoughts of others that to think for itself, to form an original opinion, was now a difficult matter. But while it was in this state another Architect came and stood by. He said: "Both of those men who have been trying to teach you the principles of architecture are wrong. They are not architects, but archæologists and antiquarians. You must see first that it is a fine ideal to create an architecture of our own, one which men may look back upon with admiration, an architecture expressive of its purpose, and the distinctive outcome of the needs of our time." The General Public thought this a fair basis to work from, so the Architect continued: 'This ideal cannot be reached by following in the steps of the copyists. We shall not reach it by slavishly imitating forms which belonged intrinsically to the pre-Christian era or to the Middle Ages. Everything has changed since then, and we must change our architecture in order that it may be more in conformity with our new requirements. The Parthenon, the Colosseum, the Gothic cathedrals—these are all very beautiful buildings, but there is no merit in duplicating them. It requires little skill to do that. So if we are to form a style of our own we must face the problems of to-day fairly and truthfully; we must use iron as iron—not as wood or stone—we must not cover our buildings with ornament which properly belongs to a fourteenth-century church; in short everything must be the outcome of to-day." The General Public and this Architect had been walking slowly along and they arrived opposite a strange building, with curious chimneys, railings like gas piping, and girders showing boldly. "But" said the General Public "the building is not finished, is it? I don't like to see the girders showing like that, and what plain doors." "Why" replied the Architect, "that is functional expression.' "Anyhow, I don't like it." "Quite right," chimed in the other two Architects, "this is all rubbish; because a thing is modern, that is no reason that it is beautiful." "What am I to do" implored the General Public "when you, who profess to know what is right, cannot agree? I believe that none of you have the courage of your convictions. You say brave things, but you do not carry them out." Then it was that the three Architects united and killed the General Public for its stupidity and arrogance.

R. R. P.

BILLIARD ROOM, 8 WEDDERBURN ROAD, LONDON, N.W. A. H. BELCHER, ARCHITECT.

Fictitious Titles. There are certain individuals in the architectural profession who, not having any practice to speak of, devote considerable time and trouble to designing sundry imaginary "jobs," to which they give such fanciful titles as, "House near T——," or "Proposed Villa at B——," generally naming some country town or village. We have an eloquent example of this in the "cul-de-sac" set aside for architecture at the Royal Academy, which is a favourite show-room for the gentlemen in question. These designs, mostly of country houses, are of the class one might describe as "tricky," designed to catch the eye, generally very prettily drawn and coloured. The plans seem to be of quite a secondary consideration, as if the architect had first sketched a pleasing elevation and then made the plan fit as best it might. One often detects in such plans awkward corners, &c., which are generally labelled as cupboards, and in some cases there is really bad planning, such as would be impossible to deal with in practice; but as the design is not going to be carried out, details like these are slurred over. Then again the elevations are often similarly at fault, and one sees parts in them which, if not impracticable to execute, show at all events bad construction, and these are slurred over in a similar manner, usually by incorrect representation, or by merely indicating, instead of drawing in boldly. The reason for all this is that the exhibitor desires to advertise, to bring his name before the public, or that portion of the public which takes an interest in architectural matters. If it were not so the designers would simply put "Design for Country House," or some other title which would show that it was merely a design done for practice. But this, one presumes, would not be imposing enough—it is much better to pretend that the house is really going to be built; and if the designer is successful in getting several of these "shams" published he appears, to the uninitiated, to have quite a large practice. At the same time one recognises that some of these designs are certainly clever, and show what the author could do had he the chance. In such cases the planning, elevations, and general get-up are good and straightforward; still, they have the misleading title. But in the majority of designs under these false titles the imagination runs riot, and generally there can be traced an unhealthy desire to be

original at the expense of good planning and construction. This practice, which tends to make people believe that the buildings are actually going to be erected when in reality they exist only on paper, is on the increase and should certainly be discouraged.

G. A. J.

The Future of South London.

VIEWS of London not older than the last century show us the south bank of the Thames barely fringed with houses; the ancient suburbs of Southwark and Lambeth just growing into towns; factories practically unknown; with a glimpse of trees even and open country just beyond. Of all its modern extensions the growth of London to the south is the most remarkable. In many respects southern London is a separate town, with industries and characteristics of its own, larger than all London at the beginning of the century, and stretching from the river to Norwood in one direction and from Charlton to Putney in the other. South London has grown outwards whilst the outlying villages have grown inwards to meet it; the result is a city larger than any European capital except Paris. In character it is suburban; the vast quarters which have grown up with such rapidity "over the water" seem to possess no metropolitan dignity, no sense of forming part of a great capital, a fact which has been commented upon by Sir Walter Besant. It contrasts strongly in this respect with Paris; there both banks are of equal dignity, the government offices are scattered on either side, and whilst the fashionable drive and promenade are on the north side the old residential Faubourg and the palaces of the Legislature are on the south; the division, however, is made by a river whose average width is barely half that of ours, and spanned by innumerable bridges. Some idea of laying out streets upon a definite plan was evidently entertained as the century grew, for the main roads of transpontine London are very wide and converge upon certain points; all those from the bridges, for instance, unite at a circus exactly equidistant from Westminster and Blackfriars, the great bend of the Thames lending itself well to this arrangement. The few fine buildings that the south side of London possesses, St. Thomas's Hospital, Bethlehem Hospital, and Lambeth Palace, are well placed; the fine church of St. Saviour's, Southwark, is, however, completely stifled by enormous buildings. St. Thomas's Hospital is notable not only for being built in separate blocks with open colonnades between—architecturally a most effective arrangement—but further for rising above the first part of the south shore which has been embanked. That this will some day be completed appears to be certain, and what a revolution, if the work be done with taste, will it effect in the appearance of the town.

At present, in spite of wide roads laid out upon a sensible system for main lines of traffic, South London, within a mile and a-half of the Thames, has an air of neglect, as if it were no true part of the great city; it is unimportant, multitudinous and commonplace. Yet it is changing and for the better. The clearance and remodelling effected when St. Thomas's Hospital was built have made a fairly good approach to Westminster Bridge, and the extension of the South-Western terminus may lead to further changes in the approach to the magnificent Waterloo Bridge. The ceaseless demands upon the ground on the north side will before long cause many large buildings for institutions, societies, hospitals, offices and schools to be built in South London, and this in its turn will lead to further clearances and rebuilding. Before many years it seems probable that the two halves of the great city will be more alike, and its southern part somewhat less commonplace and semi-suburban that at present.

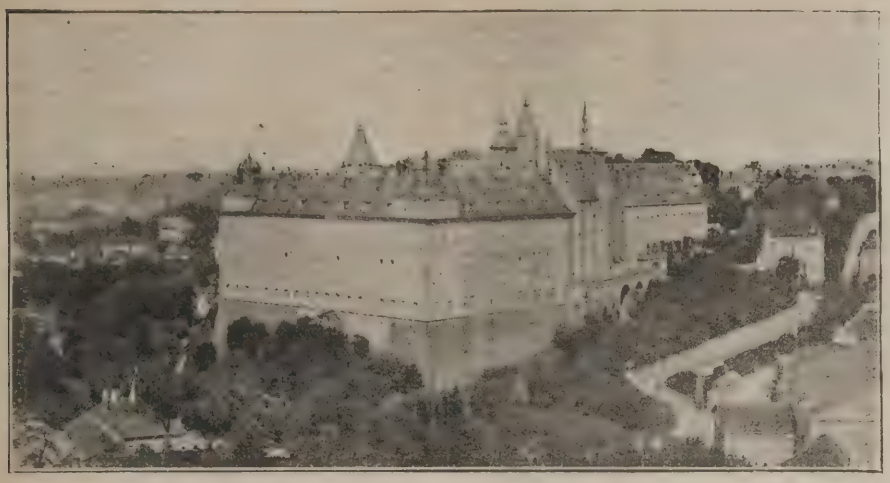
J. C. P.

On Reflection.

Another Unsatisfactory Competition.

ARCHITECTURAL competitions have become a by-word. Mr. E. S. Prior says: "That there is a practical failure in the method of architectural competition has been acknowledged for thirty years. It clearly proposes a false standard to its competitors, that of pleasing by representation, not by work." Mr. James Brown Lord, the well-known American architect, says: "I detest competitions. I believe that in all art works they are utterly wrong—in my opinion they are the degradation of every art profession they enter into." Mr. William Emerson, the President of the Royal Institute of British architects, says: "I cannot help expressing the opinion, based on years of experience, that whether looked at from the point of view of the client who desires to obtain a good building, or of the architect who wishes to do himself justice, or of the general public interested in fine architecture—architectural competitions are a failure." And it would be easy to go on quoting similar censures from scores of leading architects. It is sufficiently lamentable that the competition is wrong in principle, but when it is unfairly administered it becomes doubly injurious. The Belfast Assembly Hall Competition is a case in point. The assessor (Sir Thomas Drew) made his award about six months ago, but, as will be seen on reference to the letter on another page from Mr. Rupert Savage (who gained the first premium), the committee have set aside all the designs sent in and have appointed a Belfast firm of architects to carry out the work. This is most unsatisfactory and unfair to the competitors. It would certainly have been better to have taken this step first. Architectural competitions waste enough time and energy as it is, but when they become useless and the author of the winning design is not given the work to carry out, it is not surprising that great dissatisfaction is felt. It is, of course, impossible to expect a committee to pledge themselves to carry out the first premiated or any other design, but we think that this should be a moral obligation on them if not a virtual one.

Sir Frederick Bramwell's Scheme.



THE latest proposal in connection with the new street to be formed from Holborn to the Strand comes from that wonderful old gentleman, Sir Frederick Bramwell. Full particulars of the scheme will be found on another page, but it may briefly be stated to consist in constructing a footway over the ground-floor shops and forming another row of shops on the first floor. The storeys above would overhang the footway for about half its width, and would be supported by columns or girders, while bridges would span the side streets; here and there a bridge would also stretch over the main street in order to make intercommunication between the upper footways on either side. The proposal is based on a faulty argument, and is not one which would produce a successful architectural result. Sir Frederick takes as his model the "Rows" at Chester, and says that as these are so picturesque, it is reasonable to suppose that an equally satisfactory effect would be produced if the same principle were carried out in the buildings that will face London's new street. But this is not so, because the necessities of London and Chester are totally different. In the "Rows" there are no shops with large areas of plate glass, but small door and window openings which leave enough walling to satisfy the eye that the lower part of the building is strong enough to support the upper storeys. All this would be changed were the same idea carried out in London. Instead of a substantial looking base we should have yards of plate glass, supporting more plate glass, which in turn upheld the upper parts of the building. The ground and first floors would be of a glass and iron architecture, and though it may be quite proper to use any material for building, provided it serves its purposes, past experience of this kind of construction does not foster the desire for a more pronounced development. In every city in the country to-day the great majority of the shops are architecturally displeasing. But the shopman insists on this great expanse of glass and the architect is equally zealous in hiding away the girders which form the real strength of the structure. There is, of course, no danger of the buildings collapsing, but as they are built at present they appear to the eye to be unstable. Under these conditions, and in view of the fact that there is nothing to warrant the supposition that the architects for the new street would improve their methods, we cannot agree with Sir Frederick Bramwell that the scheme would lend itself to picturesque architecture. Moreover, who would bear the cost of erecting such expensive buildings? The London County Council would not approve the much more moderate scheme of the Royal Institute of British Architects for erecting covered ways over the pavements, and we do not for a moment suppose that this later scheme will meet with their approbation.

Flats.

MR. LEONARD SNELL disclosed to the members of the Auctioneers' Institute last week his dream of flats, residential flats, where one could enjoy all the comforts of a home for a very nominal sum. His ideal is a combination of the flat and the hotel—a building in which dining and reception rooms are provided for the common use of the tenants, who have their private rooms upstairs. Doubtless the idea is capable of extensive application and for a certain class it is specially adaptable. The manner in which rents are increasing is certainly enough to make one search anxiously for a way out of the difficulty, but we are inclined to believe with a contemporary that the average man is rather more disposed to being whisked by twopenny tubes or penny balloons to rose-covered cottages in the suburbs than herding in a hotel-flat amid the din and hurry of a great city; Mr. Snell, however, is of opinion that the cottage (or villa) idea is idyllic; a few months travelling on the South-Eastern and Chatham Railway is calculated to knock romance on the head. By crowding us all into great flats he would reduce the area of London it is true. It is no doubt farcical to suppose a building to pay when the ground rent amounts to one-third of the gross rental. As for applying the idea to housing: this has already been done in a modified way by various corporations, but the result is not very satisfactory.

Guildford Town Hall.

THE Corporation of Guildford have resolved to pull down the Town Hall in the High Street, Guildford. Although not boasting any great antiquity, having been erected in the year 1814, it is a dignified and appropriate building, and its demolition would be a distinct loss to the town, which, notwithstanding the serious inroads which have been made upon it by speculators, still retains much of its ancient charm and picturesqueness. The Society for the Protection of Ancient Buildings has memorialised the Corporation against the proposed removal of the Town Hall, and in doing so the Society is only acting up to the spirit of the manifesto published at its inauguration in favour of the preservation of all buildings of every age or style if possessing any artistic or archæological value.

ALTENBURG CASTLE FROM THE SOUTH-WEST.

ALTENBURG.

BY F. H. CHEETHAM.

ON the night of July 7th, 1455, the Princes Ernest and Albert were stolen by Kunz von Kauffungen from the Castle of Altenburg. In all probability the Prinzenraub was not so very serious an affair. There is no evidence to show that Kunz intended any bodily harm to the boys. His intention most likely was merely to hold them as hostages till his own grievances should receive attention from the Elector, their father. But fate was cruel, and Kunz paid for his rashness with his life. Probably the whole incident would be quickly forgotten, for there seems to be no trustworthy record of the event preserved at Altenburg Castle, and, indeed, you are told there that it was not till long years after that people began to write about it and treat it as of historical importance. There is now a whole literature on the subject in Germany, and of the many visitors to Altenburg to-day it may fairly be computed that two-thirds of them are drawn there to see the town and country of the Prinzenraub.

I am not going to tell the story over again, although I believe it is very little known in England. It can be read, however, in one of Carlyle's essays. This essay he contributed to the "Westminster Review" in 1855 at the time of the four hundredth anniversary of the stealing. The chief interest of the incident to most English people lies in the fact that our own Royal Family is directly descended from one of the princes stolen by Kunz von Kauffungen. Each of the boys became the head of a long line of princes, to one of which—the Ernestine line—belonged the late Prince Consort. The Prince of Wales is the thirteenth in direct descent from Prince Ernest, the victim of the Prinzenraub.

So we go to Altenburg for the sake of the Stolen Princes. But we find more to interest us there than is contained in this old story of the Middle Ages.

Altenburg is a town of very considerable interest, both architectural and historical. It is now the capital of the Duchy of Saxe-Altenburg, and is the residence of the Duke. It lies about twenty-five miles directly south of Leipzig. Travelling from Leipzig towards Bavaria, the railway cuts through a portion of the Duchy of Saxe-Altenburg, and at Altenburg itself there is an important station. But from the train you can see very little of the town, and nothing at all of the castle, which is its glory. An electric tram will take you from the station to under the very walls of the Schloss, but that is almost the only reminder of the nineteenth century at Altenburg. I have not forgotten the inevitable War Monument and the statue to Emperor William I. But these are now necessary adjuncts to a German town, and are hardly more noticeable than the street lamps and the letter boxes. There is a refined, quiet, dignified air about Altenburg that we find in small German capitals; an absence of manufacture and smoke; a blending of the Middle Ages with the "elegance" of the eighteenth century.

He would be a bold man who would attempt to give even an outline of the history of Altenburg in a few paragraphs. The native population form a distinct race, and wear a picturesque costume of their own. They are of Wendish origin, and are supposed to be the descendants of a Sclavonic tribe which emigrated from the shores of the Adriatic more than a thousand years ago. The history of German States in the Middle Ages is too confusing for most of us who have not abundance of leisure to investigate. We take Dukes, Electors, and Emperors as we find them. Coming down to later times, Altenburg was, in 1603, raised to the dignity of an independent principality. On the extinction of the reigning house in 1672 it was joined to Saxe-Gotha, and so it continued down to 1826. On this latter date, on a renewed division of lands, Altenburg became again the capital of an independent State—the Duchy of Saxe-Altenburg. The present Duke Ernest is the grandson of the founder of the new line.

The Castle dominates everything in Altenburg. It is magnificently situated on a rock, about 300ft. high, in the middle of the town. It is exceedingly irregular on plan, and is a confused jumble of architecture. The castle of the twelfth and thirteenth centuries seems to have consisted of three separate parts, used for distinct purposes, and divided from one another by walls and moats. One of these buildings was the residence of the representative of the Emperor, and was called the Smaller Castle. The Emperor is said to have often held his Court here, so that the buildings must have been of a fair size.

The Castle to-day is really a composite building, which is the outcome of these three former buildings being gradually absorbed one into the other. The courtyards are now connected, and form a very irregular space, round which the various buildings are grouped. There have been so many fires, and so much consequent rebuilding, that the confusion of architecture is at first sight rather bewildering, though not unpleasing. There has been no copying of old styles, so that each part bears the mark of its age. It is all honest building, even if not always beautiful.

The Castle suffered very much in the Thirty Years' War, being repeatedly plundered. A good deal of building went on in the eighteenth century. In 1706–8 what is now the ducal residence, the great square building facing west, was built in place of a former building erected in 1518 by Frederick the Wise. In 1718 the Prinzenpalais (since burnt down) and the present approach to the Castle were built. In 1813, the year of the battle of Leipzig, the Duke then residing at Gotha, the Castle was used as a hospital. After the refounding of the duchy in 1826 the ancient ducal seat was worthily restored.

But the days of fires were not yet over, and in 1864 the great Salle, or Throne Room, and the wing adjoining were destroyed. A second fire destroyed the Prinzenpalais, and both of these were rebuilt between 1865 and 1870.

The foundations of the Schlosskirche are said to date from the twelfth century, and between this date and 1870 the architectural history of Altenburg Castle is comprised.

The approach to the Castle is by the sloping roadway already referred to as having been constructed in 1718. It leads us to the principal entrance, through a classic gateway flanked by obelisks of red porphyry, with statues of Hercules and Minerva. On our left is a raised platform, above which rises the Schlosskirche. Here we are face to face at once with that contrast of Gothic and Renaissance which makes Altenburg Castle so picturesque a jumble. The church itself is a rather florid Gothic of the fifteenth century, as seen from the outside, whilst on each side of it are the long straight walls of the early eighteenth century, with their monotonous square windows and conspicuous absence of decoration. Inside the courtyard the same contrast is everywhere seen—behind us the Gothic church, opposite to us the round tower known as the Mantelthurm, a relic of the thirteenth century, to our left the remains of a line of galleries in the style of the Italian Renaissance. Beyond these is the eighteenth-century ducal residence, whilst prominent from whatever point of view we regard the Castle rises the Hausmannsthurm, a round tower over 100ft. high, the product to-day of the fourteenth, fifteenth, and seventeenth centuries.

ALTENBURG CASTLE FROM THE NORTH.

The buildings of 1706–8 were pushed so far over the face of the rock on the west side that very high foundation walls were necessitated. This it is what gives the Castle so plain and stern an appearance seen from this side. The cellar storey, which is vaulted, lies about 90ft. or 100ft. above the street. The interior of the ducal residence, which can be seen when the Duke is away, is not in any way remarkable. There is a solid simplicity and splendour about it which never runs into excess or bad taste.

The new Great Hall, or Throne Room, was built from the designs of Stüler in 1865–9. It is 92ft. long, 46ft. wide and 33ft. high. It is a handsome apartment, with much more restraint in the decoration and colour than we expect to find in royal or ducal palaces, especially in Germany. Modern Germany is responsible for so much that is architecturally bad that we are apt at times to think that she can produce no thing good—which is not the case. Unfortunately, the bad work is that which, somehow or other, gets illustrated.

The Kirchensaal was built in 1609, and, as its name indicates, forms a kind of entrance apartment to the church from the palace. It is 60ft. long and 30ft. wide, and has two Ionic pillars in the centre to support the ceiling, which is not very lofty. This room contains portraits of the Wettin princes of former and modern times. From the Kirchensaal you enter the west gallery of the church (Schlosskirche). The church is used by the town, the people sitting below, while the Duke and Court occupy the galleries. The ducal pew is in the west-end gallery, and is entered from the palace. The foundations of the church, as we have already noticed, date from the twelfth century. The greater part of the structure of the present building was erected during the fifteenth century. It was renovated in 1549, and again in 1645–8. During the latter years the galleries were added, the pulpit having been put in fifty years before. The galleries and fittings generally are of a florid Renaissance character. The effect on entering from the Kirchensaal is rather distressing. The freshness of gilding and paint has all gone, but it is an open question whether that is a loss or a gain. Birds, masks, coats of arms, death's-heads, and a general exuberance of ornament give a bizarre feeling to the place little conducive to the spirit of worship. Despite its Gothic setting, the seventeenth century cries out loudly all around you. The ducal pew facing the altar reminds you of an opera box, and is quite as comfortable. But we must not look to Lutheranism for the beauty of holiness.

There is an excellent model of the Castle—by that I mean the whole range of buildings—in the museum located in what were formerly the pages' quarters. As you are shown through the museum and armoury first, you can "take in" the plan and disposition of the building from this model before you are conducted over it. In the museum is an interesting collection of relics of the Prinzenraub. The guide-books tell you from which window the princes were stolen, but the custodian will inform you that as a matter of fact nobody knows from which part of the Castle the theft took place. What is certain is that the window of the guide-books did not exist in 1455. But it is quite possible that the room where the boys slept was in this part of the castle, in a building which has since disappeared.

SCHLOSSKIRCHE, ALTENBURG: LOOKING EAST

SCHLOSSKIRCHE, ALTENBURG: LOOKING WEST.

An examination of the visitors' book kept at the Castle shows you that very few English people go to Altenburg. Apart, however, from its historic interest, there is much to attract visitors to the town. The Rathaus, in the market-place, is a picturesque building with an octagonal tower, built in 1564. The Bartholomarkirche and the Brüderkirche both possess some architectural interest, and Luther is credited with having preached in both. The Brüderkirche, we were told, is shortly to be pulled down. The modern buildings are of a quieter Renaissance type than modern Germany sometimes offers. English visitors to Leipzig are so numerous that it is a wonder, and a pity, that more of them do not find their way to Altenburg. The historic interest of the Prinzenraub is enough to attract the tourist, but it is to be feared that few English people are familiar with the story that draws so many Germans yearly to pass through the gateway of Altenburg Castle.

CHURCH BELLS.*

BY HENRY ROSE.

BELLS in one form or another have long been associated with religious observances, not only in this country but throughout Christendom. I say in one form or another because, as we shall see, they were not always as we know them now, either in shape or material.

If we turn to the Bible we find them mentioned twice in the Book of Exodus as forming part of the vestments to be provided for Aaron as High Priest—"a golden bell and a pomegranate upon the hem of the robe round about"; and it is clear that mere needlework cannot be implied, as the verse goes on to say, "his sound shall be heard when he goeth into the Holy place and when he cometh out," and they are again mentioned as having been provided. There is another mention of bells in a rather obscure prophetic passage in the last chapter of Zechariah: "In that day shall there be upon the bells of the horses Holiness unto the Lord." There is no indication of a bell in any form on any of the mural paintings or mummy cases of Egypt, so we may fairly conclude that they were unknown, bearing in mind the careful manner in which the various employments of those times are depicted, and the diagrammatic precision with which accessories of all kinds are introduced.

The Assyrians or Babylonians, on the other hand, made great use of bells on the harness and trappings of their horses, as can be distinctly seen on the bas-reliefs of Assur-barnipal in his hunting chariot, now in the British Museum; about twenty of these bells were discovered by Sir Henry Austen Layard during his excavations at Nimroud near the site of ancient Nineveh. They are of bronze, consisting of ten parts of copper to one of tin; the largest are of about 3in. diameter; they taper but slightly; most of them are fitted with iron clappers, many of these being in the form of a ring.

Metal bells were well known to the Greeks, who were in the habit of beating brazen bells at the decease of a friend to scare away the Furies; and to the Romans, who had different names for them according to the uses to which they were put, such as the Tintinnabulum, which announced the time when the public baths were open.

As to the origin of the use of a bell, we find in a work on the history of the world compiled by Eutychius, who was Patriarch of Alexandria in 870 A.D., that the first bell was an instrument of wood which Noah caused to be struck three times to call the workmen to their work upon the Ark. This is also alluded to in the same connection in a twelfth-century Persian work on theology, and is quoted by Fletcher in his "Notes" on Nineveh.

Large bells are hung low down in Buddhist temples in Burmah on which women strike as they pass. Two brass bells on elaborate stands were taken from the Imperial Palace in Pekin quite recently, and are now, I believe, on their way to the Victoria and Albert Museum. Bells are not used in Mahomedan mosques, the call to prayer being made from the minarets by the muezzin, most probably from a desire to depart as much as possible from Christian usage, though according to the Koran bells hang on the trees of Paradise and are set in motion by winds from the Throne of God as often as the Blessed wish for music.

A curious custom, which is still observed at Toledo, would seem to suggest that wooden clappers were in early times used instead of bells, since in connection with the Mus-Arabic ritual as practised in one of the chapels of the cathedral, a wheel provided with wooden clappers (which fall upon one another when the wheel is revolved) is used at certain times during the service. This ritual dates from the time of the conquest by the Moors, when many Christians remained in Toledo and were permitted by their conquerors to maintain their religious observances, though probably in a modified form.

The use of wooden clappers in the place of bells would appear to be traced from India (where they were in use at a very remote period) to Arabia and so to Spain, where many instances of the survival of Arabic customs still exist (such as the absence of seats in churches, matting on the floor in choirs, and the mantilla worn over the head by women). Wooden clappers on a large scale are also very general in the towers of their cathedrals and large churches, and are used as substitutes for bells during holy week, both for striking the hours and for calling to worship. I have heard them so used at Cordova and the effect was very remarkable, if only from the great contrast between the noise so produced and the music of a peal of bells. A wooden clapper is also still in use in France, certainly at Valognes in Normandy, where, during the progress of the service frequent signals are given to the choir by two rapid strokes with two small boards.

The oldest bells of which we have any record were not of any size, and they consisted of wrought-iron plates riveted together generally square on plan; one at Cologne is said to be of sixth-century work. There is a twelfth century hand-bell which used to be carried before the Viaticum in procession that has frequently been reproduced in cast brass; it is

* Paper read before the Discussion Section of the Architectural Association on November 2nd, 1900.

pierced and decorated with the emblems of the four Evangelists. Illuminations in thirteenth-century psalters show small bells hanging from a frame and beaten by hand. Perhaps the oldest known cast bell of any size is one at Siena, which is cask-shaped, three feet high, and gives a very sharp sound; it dates from 1159.

The first notice of church bells in this country occurs in the writings of the Venerable Bede, who mentions them as being in use in the seventh century.

The year 940 is given as the earliest date at which bells were cast in this country, but the actual date is disputed. They were ordered to be rung before the Divine Officers in the Basilicas by Papal decree in 604, from which date they gradually became general throughout Christendom.

Casting.

The process of casting a bell of say 30in. diameter and an approximate weight of 6cwt. may next be briefly described. The nature of the bell metal to be used has to be determined, and this, in accordance with the general use since the sixteenth century, will probably consist of 4 parts of copper to 1 of tin. The proportions of the bell will also be dictated by the use in vogue since the same date, the thickness of the edge to be $\frac{1}{15}$ of the diameter and the height $\frac{12}{15}$ of the same, the inner and outer curves being set out in section full size. A *crook* or double compass of wood is cut to the shape of the curves and fitted to a pivot on a stake firmly fixed in the bottom of the casting pit. A *stuffing* of brickwork with provision for a fire inside is constructed around the stake, and on it is padded the *core* of fine soft clay and hair worked to the inner leg of the crook, and after this has been well greased the false bell is fashioned with more clay to the template furnished by the outer leg. Any inscription or ornaments are moulded in wax and stuck on, smeared with grease, and lightly covered with the finest clay, the whole surface being then greased and thickened out with a solid *cope* or *mantle* over the outside of the clay bell. The fire is next lighted and the whole baked hard in a kiln or oven, the grease and wax being allowed to escape. The cope is then carefully lifted and the false clay bell broken up and removed, after which the cope is replaced and molten metal poured in and left to cool for some hours. Of late most bells of more than 18in. diameter have been "loam cast," that is, without a model, the cope being formed inside a metal cope case, and inscriptions, &c., stamped with dies in the cope. The pattern for the crown of the bell with the canons is generally baked separately and added before the actual casting takes place.

If everything is satisfactory the bell should have one note, the consonant, and when this is distinct and clear the bell is true and in tune. In order to test this the bell is slung, and when tapped on top should give forth a sound one octave above the consonant; at one quarter from the top the fifth of the octave, at 2½ quarters lower down the third of the octave, and on the rim the keynote or consonant of the bell. It goes without saying that to deliver the verdict with authority and in order to give it due weight requires the trained ear of an expert possessing considerable knowledge of the science of music."

The tone is after all the most important factor since, to quote Sir Edmund Becket, "A set of cast-iron pots might be in as perfect tune among themselves as the finest peal of bells in the world, and the tune or note of a bell can be altered a little by cutting, whereas the tone or quality of the sound is incurable if it is bad."

The precise thickness of metal as well as the exact proportion between the copper and tin are both matters of much technical interest and are points on which founders differ and have much to say, but, as mentioned above, four to one is the average mostly in favour, though about two hundred years ago both here and on the Continent it would appear to have been as three to one. Rules are also in force for the clapper, which is of iron, and should weigh about $\frac{1}{75}$th of the bell. Continental bells differ in shape from ours in being longer and more approaching to that of an inverted flower-pot, but I do not think there is any room to doubt that ours are better in every way.

Sentiment might seem to indicate that silver should enter into the composition of the founder's metal. How often one hears the silvery tones of old bells alluded to with admiration. What a silvery tone may mean I do not quite know, but it is very doubtful if it is due to any admixture of silver with the bell metal, since no trace of it has been discovered in old bells that have been melted down, and Sir Edmund Beckett—now Lord Grimthorpe—proved many years ago by experiment that no advantage is gained by its use. On the other hand the monkish chronicles of Charlemagne (887) make mention of a founder who fraudulently appropriated 100lbs. of silver intended for a church bell, which, when hung in the tower, was practically mute; the founder was sent for and proceeded to ring it, but the dumb-bell exercise proved fatal to him, for it fell and crushed him to death. The hidden silver was discovered and given to the poor. Some Franciscan missions in California have bells, probably cast in Spain in the sixteenth century, which are said to be half of silver and half of copper. In Hungary guests are frequently invited, as elsewhere, to attend the casting of bells and often throw silver coins into the molten metal. Cast-steel bells are made by a Sheffield firm, but they are not equal in tone to those of bell metal, and of late tubes have been used; but this is a paper on bells, so we can omit any further allusion to tubes. For small bells and house-bells zinc and lead are sometimes employed. Glass has been tried for bells of 14in. diameter, but the material, though undoubtedly elastic and sonorous, would not stand the heavy blows required for a large bell; indeed, a glass bell equal in power to one of bell metal would have to be at least as large again, or of about eight times the weight, so that glass as a material is out of the question.

Of bell-founders in this country there are several firms of very high reputation. Many of the London City churches had their bells cast by Rudhall, of Gloucester; Messrs. Mears and Stainbank, of Whitechapel, are the successors of a business started by one Robert Mot in 1570, and carried on by Lester and Peck, who in 1750 cast a peal of bells for a church in Philadelphia; Messrs. Taylor, of Loughborough, who in 1881 cast the great bell for St. Paul's Cathedral (weighing about 17 tons), and the peal of ten bells for the Imperial Institute, are well known; Messrs. Gillet and Bland, of Croydon, who supplied the carillon for the Manchester Town Hall; Messrs. Warner and Sons, of Spitalfields, who cast Big Ben (16 tons), and the four quarter bells (8 tons) for the Houses of Parliament in 1856, and many other firms established up and down the country. Messrs. Warner have just cast a set of five bells for the Colchester Town Hall, the biggest weighing 25 cwt; this operation they were kind enough to invite me to witness.

The parts of a bell are as follows:—The "canons," by which it is fastened to the stock, the "crown" or top of the bell, the "waist," and the "lip" which forms the lower margin. The "sound bow" or thickest part is between the waist and the lip; it is here that the clapper strikes; if 1in. too high the full tone is not given, and 1in. too low may crack the bell. The clapper hangs from the "bow staple," and has a prolongation below the striking surface termed the "flight."

ALTENBURG CASTLE: THE MANTELTHURM.

Inscriptions.

These are nearly always to be found on bells, and many of them are of great interest apart from the date of the casting which they often give. Perhaps the oldest authentic bells in this country are those at Attleborough, Norfolk, dated 1281; at Claughton, Lancs., dated 1296; and the treble bell at Cold Ashby, Northamptonshire, dated 1316. A few examples may be of interest. At Passenham, Northamptonshire, there are five bells, three of which have inscriptions as follows:—

"Sancta Maria ora pro nobis" in old English letters and no date; "Richard Chandler made me 1711"; and "A trusty friend ys harde to finde 1585"

At Bolton-by-Bowland, Yorks:—"+ Sce Paule ora pro aiabus Henrice Pudsey et Margarete Consorte sue +"; no date is given, but a Pudsey of the time of Henry the Sixth (1422-61) is buried there, on whose tomb is incised his figure, that of his three wives and twenty-five children. At Rowston, Hereford:—

ALTENBURG: THE RATHHAUS AND MARKET PLACE.

"Christus-est-via-veritas-et-vita." Elsewhere we find:—

"To call the folk to church in time we chime.
When joy and mirth are on the wing we ring.
When we mourn the departed soul we toll."

also

"Funera plango, Ful'gura frango, Sabbata pango
Excito lentos, discipo ventos, Paco cruentos.'

or,

"Death's tale I tell, the winds dispel, ill feelings quell.
The slothful shake, the stormclouds break, the Sabbath wake."

At Chaddesden, Derbyshire, three bells:—"God save his Church 1652"; "All you that hear my doleful sound, repent before you come to the ground 1742"; and in old English letters "Celorum Xte placeat tibi rex sonus iste."

The longest inscription is on a bell at Glasgow Cathedral dated 1790, setting forth its founding in Holland 1594, its damage at the hands of unskilled workmen, its re-casting in London, and "Reader thou shalt also know a resurrection—may it be unto eternal life."

It is out of the question to include in any detail a dissertation upon belfries, bell-towers or bell-cots, but a few general remarks seem demanded in so far as they bear upon our subject, as church bells certainly have a direct bearing upon them in more senses than one. Broadly speaking, an English church tower with its great spread of buttresses may be taken as being better adapted for the support of a peal of bells with its enormous weight of swinging metal than the stilted proportions of an Italian campanile, which is so small on plan in relation to its height. Detached belfries, both of stone and wood, are common in Northern Europe, and in Brittany they sometimes consist of a large wooden frame standing in the churchyard without any roof or covering whatever.

Bell-cots are rare in Northern Europe (including Great Britain), but they are fairly common in Central France and Italy, and generally contain the sanctus or angelus bell, which is rung at 6 a.m., at noon, and at 6 p.m. The mid-day angelus was instituted by Louis the Eleventh, (1461-83), and the custom still survives in certain parishes in England. The small bell in towers generally known by bell-ringers as the "ting-tang" is probably the old sanctus bell, either re-hung or re-cast and re-hung. It is called the "Wackerell" in churchwardens' accounts, as at St. Andrew's, Canterbury, in 1510. A small bell was removed from the tower of Steeple Aston, Oxon, at the end of the seventeenth century for use as a school bell. In 1865 a new one was given. It would be interesting to know what has become of the old one, as it was no doubt originally a sanctus bell. There is also a small bell at Tottenham Church captured at Quebec and presented to the church in 1801, and a small bell from a church near Ruthin, N. Wales, dated 1723, was exhibited at the Church Congress at Rhyl in 1891. Tradition says that until early in the nineteenth century it was always placed on the altar step during service by the churchwardens.

Sometimes, as at Nuremburg, small bells for use at the altar are attached to a wheel made to revolve by an endless rope working over another wheel fixed near the floor level.

Methods of Hanging Bells.

The hanging of a peal of bells is an important matter for the consideration of an architect. That bells badly hung can cause the fall of a tower was proved at Vienna in 1831, when a bell of 57cwt. which had been hung in 1854, but not used until 1833, came down, bringing the tower with it. The tower was too small for the bells, or the bells were too large for the tower.

Too much care can hardly be exercised in hanging bells in their carriage or "cage," or in fixing the cage itself, which should be of stout oak well pinned and bolted, and stiffened with diagonal bracing in order to meet the strain of the swinging bells. It is well to bring the weight down as low as possible and to arrange the joists and wall pieces so as to minimise the strain on the tower, which must eventually take the whole weight either on an offset or on corbels, unless, as sometimes happens in old examples, the diagonal framing is brought right down to the ground. The holes in the centres of the floors must of course be large enough to admit the largest bell of the peal, and a stout beam must be provided above the bells to take the tackle by means of which the bells are hauled into position. It is very essential to provide a floor between that of the belfry proper and the ringing chamber—which latter should not be less than 16ft. in height—or the ringers will be deafened. The bells should not be crowded; plenty of room should be secured for access to them without danger when they are swinging. Care should also be taken to secure the joists being so placed that the ropes can descend clear of the bells direct from the wheels. Wedges should never be allowed to be driven in between the ends of framing and the walls; if the cage is found to be racking it should be strapped and bolted afresh, or, if swinging the bells is considered dangerous, the safest plan will be to ring them from the clappers alone.

It has been stated that some of the bells should swing at right angles to the others and so neutralise the effect of the swinging, but this is obviously an error, since the mechanical result of such a proceeding can only produce the resultant of the two forces. A better plan is to see that they swing opposite ways as much as possible, that is to say, if they are hung north and south, whilst one big bell is going north the other should be going south.

The bell-wheel used for all bells of more than 18in. diameter is comparatively modern, dating probably from the end of the sixteenth century, previous to which the half-wheel was used, an example of which is still in use at Dunchideock, Devon. I have recently seen one of still simpler construction in the low tower of Carteret Church in Normandy, where a single bell hangs below a low plain stone spire. A still earlier method was a long lever attached to the stock—the larger the bell the longer the lever—as now in use at Xanten in Rhenish Prussia, where, when the bells are only to be rung softly, the clapper is pulled back near the lip of the bell so that a very slight pull on the lever causes the bell to sound.

At Evreux are two west towers, the southern of which has a wooden slate-hung spire resting on the top of the tower walls. The lantern or lower portion of the spire is framed together with diagonal bracing and a central post; wooden wedges and clips are let in to the post for supporting the ties. Above this framing comes the cage proper carrying three bells each of about 3ft. diameter; the louvres are below the bells, thus directing the sound down upon the town below, and are provided with a raised ledge on their inner edges, which seems a wise precaution, since it is the wooden construction which requires protection, not the bells. In Spain and Italy bells are generally hung open to the air and no doubt are heard at a greater distance in consequence; indeed, in Spain, they are often absolutely uncovered, hanging in wrought-iron frames on the tops of the towers. The two big bells 6ft. in diameter at Evreux hang in the north tower, and are each rung by four men who step off the framing on to planks projecting from the stocks at right angles; handles are provided on the framing to hold on by. At Chartres a platform is fixed between the four bells in such a manner that four men can ring them by stepping on the levers, each man being able to assist his neighbour.

Ringers.

A great change for the better has been effected in the manners and customs of bell-ringers. Scenes of drunkenness which would have been disgraceful anywhere, and were additionally so inside a sacred edifice, were quite common at the end of last century and at the begining of the present one. The change was not effected without friction, it being much resented that the parson should exercise any control whatever over the belfry or the ringers. Only on his first arrival was it a recognised custom that the new rector should enter the church alone and ring one of the bells; many persons counted the number of strokes and believed they represented the number of years he would hold the living. At St. Peter's Mancroft, Norwich, is a jug known as a ringer's jug; it holds thirty-five pints! At St. Edmund's, Salisbury, is an entry in the accounts dated 1646: "Ringing the Race day that the Earl of Pembroke his horse wonne the cup. 5 sh."

These two facts, together with ringers' rules found here and there, show what bell-ringing had descended to. The following rhyme is painted on a framed board still hanging in the ringing loft at Ilminster:—

ARTICLES FOR RINGING.

There is no music played or sung like to five bells if are well rung,
Then ring them well as er you can silence is best for every man,
Be sure in Ringing make no mur Pull of your Hats also your spur,
And if a bell you overthrow then pay you must before you go
Now sixpence is ye usuall pay come throw it out and don't say nay
For if you don't and be not willing swear but an oath you loos a SHILLING 1740.

Societies of bell-ringers have been instrumental in keeping up the better traditions of the art in large towns, and frequently ring a series of changes known by different names, of which a "treble bob major" may serve as an

example. The oldest society in London is said to be the Compaine of the Scholars of Cheapside, which was founded in 1603.

Chimes.

Some confusion is felt at times as to the difference between chiming and ringing, or as to the definition of a peal. A chime should be a set embracing the eight notes of the common scale. The smallest number that may be termed a chime of bells is five, the usual number being nine, which enables a flat seventh to be added to the scale. To chime implies that the clappers only are swinging or the bells struck with hammers, the bells remaining stationary, or swung only so far as to cause the clapper to strike, as on the Continent.

For a peal we should require three or more bells in harmonic succession, which may be rung together—firing the balls—or successively, but it is not possible to play a tune upon them. A set of the first, third, fifth, and eighth will constitute a peal. To ring a peal implies that the bells are swung up.

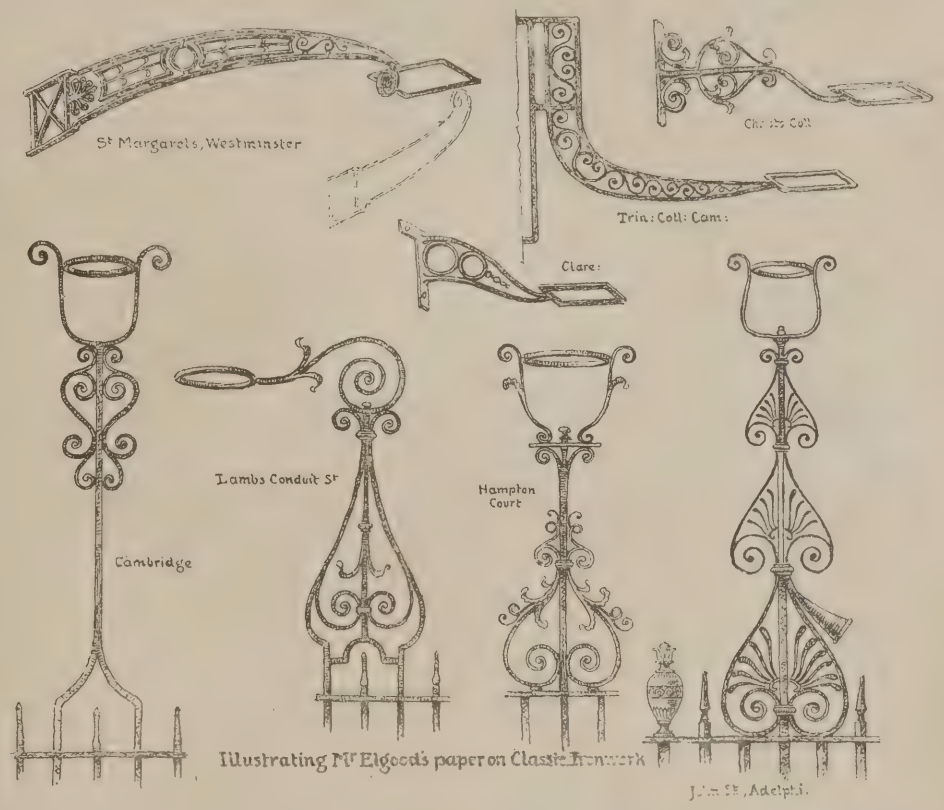
Change ringing is altering the sequence in which the bells are rung or chimed. The formula for the number of changes possible is obtained by working up from two bells, which obviously gives two changes; for three bells we multiply the 2 by 3 = 6 changes; for four bells we multiply the 6 by 4, giving us 24 changes; for five 24 × 5 = 120, and so on, eight bells allowing 40,320 changes. It has been calculated that it would take ninety-two years to run through all the changes upon twelve bells at two strokes per second.

Tolling is, of course, the ringing of a single stroke at funerals or deaths; the toll is always rung on the heaviest or tenor bell. The word is by some derived from "tollere," to raise; but it is probably merely a case of onomatopœia. This single stroke on the big bell is generally called the passing bell, and is rung at intervals of one minute. The custom is alluded to by the Venerable Bede; and it is not improbable that at one time the number of strokes and their grouping may have indicated the age and sex of the dying, as also his or her status in life. According to an old saying: "When the bell begins to toll, Lord have mercy on the soul," and as the 67th canon of the English Church has it:—

"Whenever any is passing out of this life a bell shall be tolled, and the minister shall not then slack to do his last duty."

At Harningham, Wilts, a muffled wedding peal is rung at the burial of a girl. To muffle a bell a leather muffler is laced round the clapper, two mufflers being used if the bell is to be raised.

Of voices in bells there are many stories told, and many allusions made to them in poetry, but as an old phrase runs: "As the fool thinks so the bell clinks," which means that one can make them say pretty much what one likes. "Ding dong" is perhaps the commonest interpretation of two bells, and will be recollected as forming the prelude to the adventures of a cat in a well, related in verse. To Tennyson three bells clinked a pleasant sound, if devoid of meaning: "The mellow lin-lan-lone of evening bells."



The rhyme which gives a conversation between the City steeples is also quite familiar. The four quarter chimes at Westminster have had the following words attributed to them: "Lord, thro' this hour be Thou our Guide, and by Thy power no foot shall slide."

In the parish of Wensleydale, Yorks, the largest in England, there is a chapel at Holbeck where occasional services are held. There are no bells in the tower, but the clerk goes up and rings a hand-bell, shouting, "He's a-coming, he's a-coming," when he sees the parson about two miles off. Before 1873, when the hand-bell was procured, he merely cried "bol-lol, bol-lol," or the voice of a bell which did not exist.

Carillons are sets of small bells of any number ranging over two or more chromatic scales upon which it is possible to play tunes. The most celebrated are hanging in the towers of churches and town halls in Belgium and Holland. They were first made at Alost, in Flanders, in 1487. There is a very fine set of thirty-three or more bells in the Cathedral tower at Antwerp; they are struck inside by their clappers, which are of wood and produce a very mellow sound. There are many more or less mechanical modes of ringing bells. At Amsterdam a key-board is used requiring a force of about 2 lbs. Pedals and spiked drums which raise levers are also not uncommon. Chimes with us are often rung by one man, the ropes being disposed in an upright frame and connected with levers striking the bells, capable of being put out of gear when the bells are swung.

Secular Use of Church Bells.

Church bells are frequently used for secular purposes and to give notice of parish meetings, or on occasions of national or local rejoicing, and here we may note that by common law any place of worship of any denomination may make use of bells. There is no distinction in favour of the Established Church in this respect, but it has been held that they may not be used in such a way as to become a nuisance and may be proceeded against accordingly, as was done in 1851, when an action was brought against a Roman Catholic [community at

Illustrating Mr Elgood's paper on Classic Ironwork

Croydon. In Derby they used to ring the church bell when fish arrived by coach. St. Alkamund's five bells were supposed to say, "Fresh fish come to town." St. Michael's three bells, being somewhat sceptical, "they stinken"; and All Saints' ten bells, as suggesting a remedy, added, "Then put a little bit more salt on them." In France state regulations were passed in 1885 controlling church bells, owing to a conflict between the Bishop of Agen and the Prefect of Lot et Garonne. The following clauses were imposed upon the Church at that time:—Art. 2. During an epidemic the mayor may, by authority of the Prefect, suspend tolling for funeral services. Art. 3. The vicar may not cause bells to be rung before 4 a.m. or after 9 p.m. from Easter to October 31st, nor before 5 a.m. nor after 8 p.m. from November 1st to Easter, Christmas night alone excepted. Art. 4. In each commune the mayor shall have the right to cause the church bells to be rung (1) for official passage of the President of the Republic; (2) the eve and day of the national or local fêtes; (3) to summon the inhabitants together or stop some occurrence which may need their united efforts, as fire, flood, invasion, riot, or all other cases of public welfare. Art. 5. Ringing ordered by the mayor to be done by the church bell-ringers, who will be paid by the civil authorities. Art. 6. No ringing, civil or religious, may exceed ten minutes for ordinary, or thirty for solemn ceremonies. Art. 7. Chiming during storms is forbidden.

All these regulations are still in force. The clauses I have quoted were ineffectually opposed by the clerical party. Clause 7 was looked upon as a blow at a popular belief that ringing the church bells could keep off or dispel a storm as we have already seen in old inscriptions. It may very possibly have at times produced currents or waves of air sufficient to disperse clouds which experience would have shown were ready to burst into thunder and lightning, and had often done so around the lofty spires. In the Middle Ages this power was no doubt attributed to the bells in virtue of their having been consecrated; indeed new bells were sometimes baptised on the Continent, and old ones, if not recast, were ceremoniously buried.

Our clerical party was fortunately more successful in a case of much more importance when, in 1652, it was proposed in Parliament "That the bells of such cathedrals as Parliament shall think fit to pull down shall be applied to public use for making ordnance for shipping." The resolution was lost by two votes, 23 to 21; one would wish to see the names of those two members rescued from oblivion.

General Remarks.

To take rubbings of bells, common lining paper cut into strips 2in. wide is best, using scraps of waste upper leather for the actual rubbing. For devices, squeezes in putty answer best, from which casts in plaster of Paris can be taken. Diameter at lip will give the approximate weight: 24in., 3cwt.; 30in., 5cwt.; 40in., 12cwt.; 50in., 18½cwt.

There is no advantage in hanging bells high on an elevated site. Tall bell towers are more suitable to a level country. Bells sound best across water, as there is nothing to impede the regular pulsation of the sound waves. Russian tallow is the best lubricant for the bell bearings or gudgeons. A water tank above the belfry is a wise precaution against fire. The cost of a ring of eight bells, the tenor being 4ft., weight 18cwt., would be (according to Messrs. Warner) about £800, including cage and hanging. The bell chamber for such a peal should measure not less than 15ft. by 15ft.

Of other bells time might permit of a mere catalogue, but that would not be very interesting, so I will go to Nature for one example—the bell-bird of South America, whose beautiful clear note has been heard at the surprising

distance of three miles. It has been well said that Orpheus will drop his lute to listen to this bird, which is also found in Australia and is about the size of a thrush and snow-white. For the effect produced on the human mind by bells of different metals and the associations that accompany them I cannot do better than refer you to Edgar Allan Poe.

Chinese bells are cylindrical in shape and their tone is discordant. The great bell of Pekin is 13ft. in diameter. The biggest bell in the world is at Moscow; it stands on a pedestal outside the cathedral, its diameter is 22ft., and its weight is calculated at 193 tons. The largest bell hung to ring in a peal is at Exeter and weighs more than three tons. Big Ben weighs 16½ tons with the clapper. Peter, of Exeter, is said to be the gift of Bishop Courtenay (1478–86), but in 1351 is an entry of 6s. for mending the Peter bell, and in 1453, 20s. for "una bauderick pro maxima campana in Campanili Boreali," in which year Courtenay was appointed Archdeacon of Exeter; so *his* gift of a rope—perhaps—has become that of a bell, and if that is so it would appear that if you give an archdeacon rope enough he will hang—a bell. In 1611 the bell was crazed and re-cast in 1676.

And last of all, the Curfew, "which tolls the knell of parting day." It was instituted by William the Conqueror, and is sometimes considered as being tyrannical; but it is a question if it was not a wise precaution when we consider that towns then consisted almost entirely of wooden houses.

Correspondence.

London Sanitary Administration.

To the Editor of THE BUILDERS' JOURNAL.

LONDON, S.W.

SIR,—A short time ago the seal of the London County Council was affixed to a set of proposed drainage by-laws to be made for the first time under the Metropolis Local Management Act of 1855. These proposals have to be confirmed by the Local Government Board before they become operative. Many of those who have made sanitation a study, and who have for several years devoted themselves to the improvement of the sanitary condition of urban populations, share my opinion that these proposed by-laws are in some respects adverse to the public interest, and that they needlessly interfere with individual liberty. The proposals also err in not being definite—a most serious defect, which must lead to difficulty where all are well disposed, and would be absolutely dangerous where the elastic law has to be administered by inspectors to a very great extent away from the public eye.

A part of the scheme is to rescind a definite by-law made under the Public Health (London) Act, 1891 (approved by the L.G.B.), and to substitute for it an indefinite one under the Act of 1855. Under the Act of 1891 it is a statutory duty of the County Council to make a by-law dealing with the subject-matter of that which it is proposed to rescind, and the question arises as to whether a by-law made under the Act of 1855 would be in compliance with the Act of 1891.

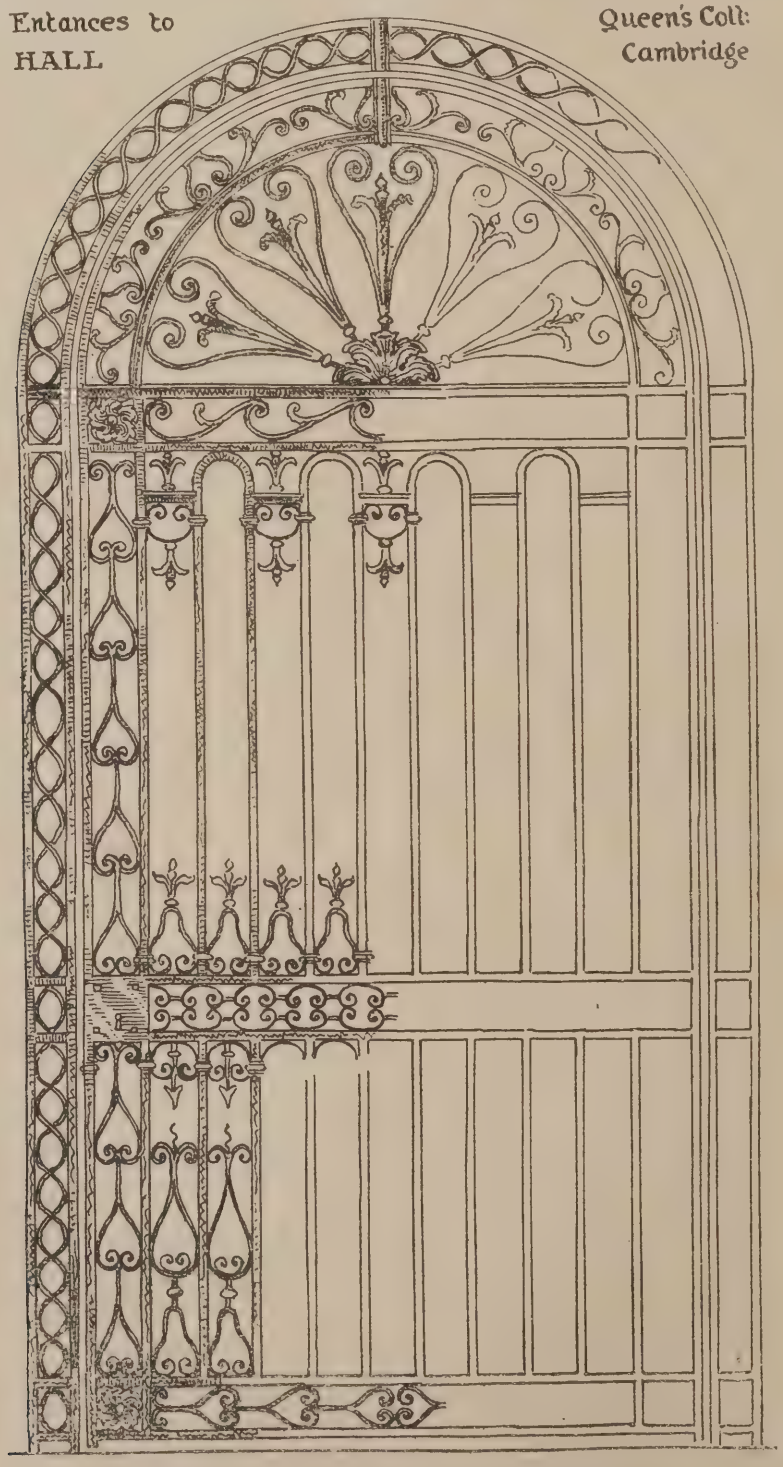
I have received a letter from the Secretary of the Local Government Board, dated November 9th, in which he says:—"I am directed by the Local Government Board to advert to your letter of the 6th instant, relative to the laws proposed to be made by the London County Council under section 202 of the Metropolis Management Act, 1855, with respect to the drainage of buildings, and to state that the Board desire that any representations on this subject may be sent to them within seven days from this date."

The County Council are advised that it will be the duty of the new Borough Councils to enforce the observance of the by-laws when confirmed by the Local Government Board, and, therefore, our central metropolitan authority having allowed nearly half a century to pass without making any drainage by-laws under the powers given by Parliament in 1855, it seems only reasonable that the new Borough Councils should have an opportunity of expressing an opinion on them before the proposals are given the force of law. A letter is now in course of signature asking the Local Government Board not to approve of the drainage by-laws as proposed by the County Council.—Yours truly,

MARK H. JUDGE, A.R.I.B.A., F.S.I.

Belfast Assembly Hall Competition.

To the Editor of THE BUILDERS' JOURNAL.



LONDON, E.C.

SIR,—About a year ago the Presbyterian Church of Ireland advertised for designs for their new Assembly Hall and central offices. The designs were sent in on March 12th, and the assessor, Sir Thomas Drew, R.H.A., awarded the first premium (£100) to my design, the second premium (£50) to Messrs. W. Hanstock & Son, of Leeds, and the third premium (£25) to Messrs. W. C. Laidlaw, of Edinburgh. I am now informed that the Committee decline to accept any of the designs submitted in the competition and have appointed Messrs. Young and Mackenzie, of Belfast, to carry out the work. I understand that Messrs. Young and Mackenzie advised and assisted the Committee in the preparation of this competition, and as these gentlemen evidently possess the entire confidence and support of the Presbyterian body I think it is much to be regretted that they were not entrusted with the work at the commencement, thus obviating the waste of a great deal of time and energy on the part of the unfortunate competitors.

I am unable to illustrate my design, as the Committee retain my drawings and decline to lend them to me for the purpose of publication.

Yours truly,

RUPERT SAVAGE.

Illustrating Mr Elgood's Paper on Classic Ironwork.

CLASSIC IRONWORK.

A SUMMARY of Mr. Thomas S. Elgood's paper on Classic Ironwork, delivered before the Birmingham Architectural Association, was published on page 305 of our issue for last week.

New Patents.

These patents are open to opposition until December 24th.

1899. — **Centrifugal Fans.** — 24,873. S. C. DAVIDSON, Sirocco Engineering Works, Belfast. The fan has a number of blades arranged obliquely to the axis of rotation, so as to enclose within them a conical intake chamber.

Hack-caps.—25,089. A. H. BEASLEY, A. H. BEASLEY, jr., and V. W. BEASLEY; all of Rockingham Iron Works, Uxbridge. The hack-cap, for protecting newly-moulded bricks and tiles, is made of a piece of plain or corrugated iron or steel, curved slightly, and furnished with a tie-rod, which also serves as a bearer or support.

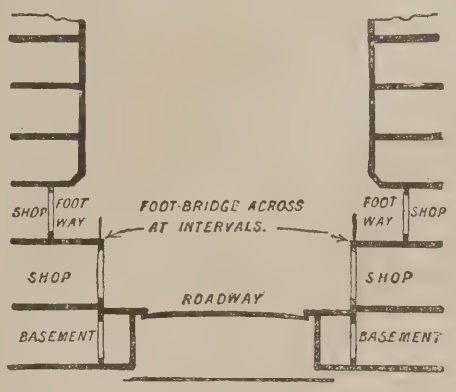
1900.—Firegrates.—15,059. E. J. PURNELL, 66 Hatton Garden, London, W.C. In order to provide a better supply of air to the fire, a box with holes and projecting nozzles is laid on the fire-bars in the centre of the grate.

Asphalt Paving.—16,167. A. METZ, 21 Rue de Rocroy, Paris. The foundation of the paving consists of cement. Above this is a thin layer of asphalt and bitumen, and on top is a thick layer of asphalt and bitumen mixed with rough gravel, a finishing being made with pulverised stone. The feature of the invention is that within the thick layer of asphalt there is a bracing of iron bars or of expanded metal.

The following specifications were published on Saturday last, and are open to opposition until December 31st. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—21,324, SKINNER, show cases. 21,493, BRAZIER, ball-cock or automatic valve for cisterns. 21,823, KNIGHT, machine or apparatus for laying bricks on buildings. 22,209, CARTMAN, pipe joints. 24,119, SVENSSON, door for stoves and fireplaces. 24,338, HILL, automatic saw-sharpening and re-toothing machine. 24,721, PFANZELTER, process for producing decoration in relief or intaglio on wood, leather, or other materials. 24,788, KITCHING, flushing apparatus for water closets. 24,887, DIGBY, electric arc lamps. 25,338, BENNETT AND BRENNAN, machines for sanding brick moulds. 25,350, SCHOLTZ, electric incandescent lamps. 25,512, WILLCOX (*Soc. J. et A. Pavin de Lafarge*), apparatus for slaking lime. 25,540, T. C. FAWCETT, LIMITED, AND FAWCETT, machinery for making bricks.

1900.—61, FRANCQ, tramway rails. 367, CRANKSHAW, CRANKSHAW AND CRANKSHAW, means for adjusting electric light and other shades. 487, KING, band-saw mechanism. 838, LAKE (*Shearman*), incandescent electric lamps. 1,141, ELLIOTT, means for fixing plaster, cement, or asphalt on wooden and other surfaces. 8,061, POCHÉ, lightning conductors and arresters for overhead electric conductors. 10,664, ORE, means for drawing down and letting up window blinds. 13,169, WARD, manufacture of broken-stone paving material. 14,569, HADDAN (Firm *Berlin-Anhaltische Maschinenbau Actiengesellschaft*), process for washing gas. 14,891, GROUVELLE AND ARQUEMBOURG, valves or cocks. 15,393, BRADLEY, gas producers. 15,650, MCDONNER, sawsets. 15,884, JAKEMAN, window-sash fastener. 16,132, EDRICK, drains. 16,847, SCHWÉERS, vices. 17,035, EDWARDS, arrangement for securing tiles to stoves, kitcheners, &c. 17,057, PLATTS AND COWEN, ventilators or air extractors.



A New Gymnasium and Reading Room at Hitchin, for the Blue Cross Temperance Brigade, situated at the back of the New Town Hall, was opened recently. The building is 78ft. long, 34ft. wide, height to eaves 14ft, and height to top of lantern 29ft. When not required, the gymnasium room can be separated by sliding doors. It is lighted with incandescent gaslight, and heated by hot-water apparatus. The building has cost, together with furnishing, about £1,800. Messrs. Barker and Son were the architects and builders.

HOLBORN-STRAND STREET.

SIR FREDERICK BRAMWELL'S SUGGESTIONS.

WRITING to the "Times" newspaper, Sir Frederick Bramwell says: "For many years I have expressed my opinion privately that, in any metropolitan improvement involving a considerable length of main thoroughfare, the old construction of the streets of Chester, known as the 'Rows,' might well be followed. No doubt most of your readers of middle age have, at some time or another, gone beyond the railway station at Chester, and have penetrated into that city; and they will know perfectly well of the construction to which I refer. But, for the information of those who have not seen this mode of dealing with the streets of a city, I will endeavour to give a verbal description, although I have little hope, judging by experience, of making myself intelligible.

"Imagine an ordinary line of street, with shops as usual at the ground floor; imagine, next, that the front wall of the houses at the level of the first floor has been taken away along the whole length of the street, leaving the upper part of the houses to be supported by columns, and that the party-walls between the houses have been suppressed for a width of, say, some 10ft. to 15ft. If this description has been followed it will be evident that there has thus been left, on the tops of the ground-floor shops, and at the first-floor level, a continuous under-cover footway, 10ft. or 15ft. wide. The front of this elevated foot-

way is protected by a parapet, and at its back are the fronts of the shops on the first-floor level. I propose that this construction, with one variation, should be repeated for the new street from north to south of London about to be constructed. The advantages are these:—(1) The ordinary street gives one shop to be let on the ground floor, and probably a basement. The proposed street would give, in addition, a shop at the first-floor level. (2) In the ordinary street the foot passengers have no protection from the weather. In the proposed street they could walk in the dry, and free from mud. (3) In the ordinary street, where the foot passengers have to cross side-streets, they must do so subject to encountering the traffic, and also where they wish to cross from side to side of the main street they must do so encountering the traffic. By the proposed method of construction there would be foot-bridges at the first-floor level, by which all side streets would be crossed, and at intervals there would be foot-bridges across the main street; also, at intervals, there would be stairs, giving access from the ground level to the first-floor level, so that persons on the ground-level foot pavement would be able to cross from side to side without having to encounter the traffic. (4) I do not pretend to be a person of taste, but I do know that such a construction as I advocate would lend itself to most picturesque and varied architecture, and would also give admirable light and air.

"The variation from the construction of the 'Rows' at Chester to which I have alluded would be the following:—I would not carry up the front wall of the floors above the first floor in the same plane as the wall of the ground floor, but would set it back, probably equal to about half the width of the footway, thereby giving more light to the first-floor shops, while still affording ample cover in wet weather. May I be allowed to give a few illustrative dimensions? Ground-floor level, 60ft. (or 80ft.) roadway, 10ft. footpath, making 80ft. (or 100ft.) between the ground-floor shops. First-floor foothpaths 15ft. wide, making 110ft. (or 130ft.) width between the first-floor shops. Front walls of the second and upper floors set back, say, 7ft., giving 94ft. (or 114ft.) between walls of the upper storeys. The first-floor shops would, I believe, command a very high rental. When sitting as arbitrator in claims for compensation, I have had it indisputably proved before me that shops bounding a paved footway thoroughfare did a far better business than those which abut upon a street."

THE L.C.C. IMPROVEMENTS COMMITTEE AND THE SCHEME.

Another long sitting of the Improvements Committee of the London County Council took place last Wednesday to consider the designs for the new Strand frontages. Again no decision was arrived at, but it is now a foregone conclusion that no single design will be adopted, but that particular features will be used from two or three of the best designs.

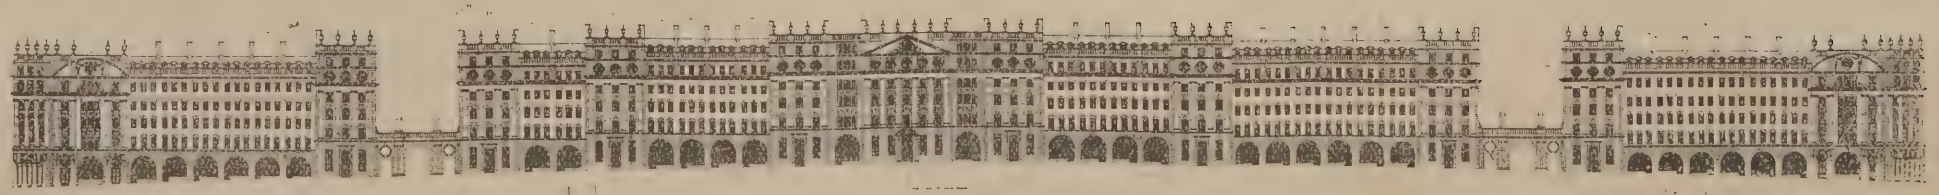
Members were discussing among themselves the scheme of Sir Frederick Bramwell.

A suggestion of a kindred nature was put before the Council by the Royal Institute of British Architects when that body was advising the Council generally on the Strand-Holborn scheme. The Institute advised the Council to construct covered ways over the pavements supported by pillars from the edge of the roadway, after the style seen in many Parisian streets. The object was not to secure a second row of shops above, but simply to introduce new architectural features to London streets. The Council would not entertain the suggestion.

Engineering Notes.

The Death is Announced of Professor G. F. Armstrong, Regius Professor of Engineering at Edinburgh University.

Proposed New Electric Line to Putney.—The London News Agency states that there is a possibility that at no very distant date an electric underground railway will be constructed between Victoria and Putney. A Bill embodying the scheme will shortly be placed before Parliament.



London Water.—Mr. E. Boulnois, M.P., presiding at last week's meeting of the West Middlesex Water Company, referred to various extensions and improvements, and said that the arrangements between the different companies were now so complete that there was no fear there would ever again at any time be a scarcity of water. He described the action of the Progressive party in promoting another Water Bill as a most wanton proceeding, and had no doubt that the House of Commons would reject any Bill not based on the recommendations of the Water Commission.

The Widening of London Bridge.—On Thursday last the Court of Common Council deussed the recommendation of the Bridge House Estates Committee to widen London Bridge, at an estimated cost not [exceeding £100,000. The Committee recommended that the footways of the bridge should be widened from 9ft. to 14ft., and that it should be lighted by electricity from the centre. It was further suggested that the balustrade should be an open one, in order that a great deal of the dust which accumulated daily upon the structure might find a means of escape into the river below. A new system of drainage is included in the scheme. The Court ordered that the report of the Committee should be printed and its consideration adjourned, and that the necessary notice should be given for Parliamentary purposes.

New Bank Buildings at Douglas, I.M., are being erected for the Isle of Man Banking Company.

NORTHERN ARCHITECTURAL ASSOCIATION.

PRESIDENTIAL ADDRESS.

THE opening meeting of the winter session of the Northern Architectural Association was held in Newcastle on Wednesday evening last, the President (Mr. William Glover, F.R.I.B.A.) occupying the chair.

Mr. Glover, at the outset of his inaugural address, gave an interesting review of the past history of the Association. They now had 53 members, 70 associates, and 59 students, making a total of 182, and it was gratifying to note that there were only three of the allied societies older than theirs, namely, Bristol, the Royal Institute of Ireland, and Liverpool; only one with more members and associates—Manchester—which had four in excess of theirs, and was the only society that had a larger number of Fellows and Associates of the R.I.B.A. He had little to report as to the progress of buildings in Newcastle, owing to the unfortunate strike that had prevailed for some time. It was a thousand pities that labour disputes could not be settled by arbitration instead of the disastrous methods now adopted.

With regard to

Housing

he said that the general principle adopted had been to erect buildings many storeys high and divided into compartments. Of course, in large cities, where the ground was very costly, this was practically the only course open, but during the last 25 years workmen's trains, trams, and steamboats had brought the suburbs of our cities in closer contact with our manufacturing centres. In his opinion, the speculative builder had been the most important agent in providing suitable houses for their poor. During the period named, within three miles radius of Newcastle, 2,492 acres had been laid out for building purposes, on about two-thirds of which the following houses had been erected:—109 detached villas, 209 semi-detached villas, 1,960 superior self-contained, 1,184 superior flats, 3,547 workmen's self-contained, 12,783 workmen's flats; and at the present time 557 workmen's flats are in course of erection.

Although his chief object was to bring before his audience the housing of the poor only, yet he thought it would be interesting to give some particulars of the middle-class residences that had been erected. He thought it was important to carefully watch the separation of the different classes of flats, so that smaller flats were not mixed up with superior ones. He would divide them into classes as follows:—(1) A flat of 20ft. by 55ft without gardens in front; (2) a 21ft. by 60ft. with a bay window on the ground floor and 5ft. garden; (3) a 22ft. by 65ft. with, say, an 8ft. garden in front, bay windows on the ground and first floors, each class to be erected on different portions of the estate to meet the requirements of different types of workmen. In his opinion it was most important that all flats should have not less than three rooms, so that the sexes could be separated.

He had had experience in estate development, and had had to do with the speculative builder. A very large proportion of the builders he had met had been anxious to build sound property: the difficulty had been for those who had honestly carried out their work to get a price to compensate them for the superior quality. In former times a good deal of shoddy work was done which brought the speculative builder into bad repute, but, in a great measure owing to the careful supervision of their city engineer and his staff, a different state of things now prevailed. It was now usual for architects to embody in their contracts for sale of land a specification wherein the size and height of rooms were carefully noted, and the sanitary arrangements carefully thought out. All living and sleeping rooms to have 14-in. walls, and proper yard areas to be provided.

He believed it would be better to leave the housing of our workmen in the hands of the speculative builder than for corporations to erect gigantic structures which had not the healthy surroundings or the domestic comfort of suburban houses. Every effort should be made to educate our industrial classes to seek for and secure a comfortable home, and to make the same their leading luxury, and inculcate within them a spirit of self-reliance, which was, or should be, the backbone of the English character. He would encourage the speculative builder by giving him an advantage over others. For example, if a single site were sold at 6s. per yard, if the builder would take six sites he would let him have them at 5s 6d., which, on an area of 150yds., would give him a profit or discount of £3 15s. per site. This would not entail much loss on the owner, inasmuch as the builder would urge on the completion of the six houses in the specified time.

It was also important that the system of advances should be as liberal as possible, and at a reasonable cost for solicitors' and architects' charges. Building and co-operative societies had done good service in helping their members to secure houses by reducing cost, in making liberal advances, and giving facilities for paying off. If corporations owning large areas of land, and private individuals who are putting land into the market for building purposes, would assist by selling it at a price that would induce speculators to take it up, he felt that the supply could be kept quite ahead of the demand.

To Reduce the Cost of the Workman's House,

the question of avenues instead of front streets should be seriously considered, as instead of paying 12s. per foot frontage for road making, it would only involve about 2s. 6d. to 3s. If front streets were adopted, he would strongly urge the abolition of back streets, which cost from 8s. to 10s. per foot, besides the continual cost of wear, tear and scavenging. He did not suggest that the area of the houses should be increased, or that the land given up as half back street should be built upon, but that the space should be devoted to garden purposes. There was an extraordinary by-law in connection with the Benwell and Fenham Urban District Council which insisted upon a 24ft. back street, with a 36ft. front street, whereas the by-laws of Newcastle insisted upon a 40ft. front street and 20ft. back street, which was much better.

The allotment system was, in his opinion, a step in the right direction. If an allotment could be secured in close proximity to the house of an artisan, it would add materially to his comforts and conveniences. This might be accomplished, if the price of land was reduced, by making the site 120ft. instead of 60ft. in depth, which on a 21ft. site would give him about 150yds. of garden ground or open space. He took the case of Corporation land at Walker. During the last twenty years there had been sold on lease about 15 acres, on which 394 houses had been erected, or about twenty-six houses per acre. At the present time there were about 62 acres laid out for building purposes, and this, on the basis of the twenty-six sites per acre, would give 1,600 sites; and if built in flats would give 3,200 separate dwellings. Taking the average family to number five, it would give accommodation for 16,000 persons. Now, though it is a well-known fact that Newcastle speculators found that freehold property had a very much more ready sale than leasehold, there being no depreciation of lease or annual payment to frighten the purchasers, he thought that, assuming this land could not be enfranchised, something might be done in the way of selling on a perpetual annual ground rent, say based on £1,000 per acre, 5 per cent. of which would equal £50 per acre per annum, or, taking 26 sites per acre, at an annual ground rent of £2 per site, would give a return of £52 per acre per annum, thus overcoming the difficulty of depreciation of lease. A ground rent of 10s. per quarter would not be a very serious charge.

During the last fifteen years the cost of a workman's dwelling had been considerably increased owing to the shorter hours of labour and increased wages, and, what was more serious, the same amount of work was not produced in the given time. Several contractors had informed him that the bricklayer at one time laid from 800 to 1,000 bricks per day, and, to quote a remark made by one of the largest contractors, "they would not perspire to do it"; now they seldom exceeded 400, and when they considered there were in the workmen's flat between 32,000 and 40,000 bricks, masonry for windows, heads and sills about double what they were fifteen years ago, it was obvious there was a great increase in the cost of such building; in fact, it and other trades affected the cost from 25 to 30 per cent. at least. A flat which could be erected for £240 fifteen years ago now cost about £320.

Increased Cost of Building.

A leading speculative builder had furnished him with the following particulars showing the difference in the nett cost, for labour only, in the several trades named for a superior "flat," of which the total nett cost was in 1890 £372 and in 1900 £505:—

Bricklayer (labour only)	in 1890, £24;	in 1900, £42
Joiner	„ in 1890, £48;	in 1900, £65
Mason	„ in 1890, £20;	in 1900, £28
Plasterer	„ in 1890, £14;	in 1900, £25

The rent of the workman's house, continued Mr. Glover, had been increased by free education and the School Board rate.

The workman was not quite alive to his own interests in making it more difficult to secure cheap and healthy homes. He was exceedingly glad to know that the proposed Town Hall and Art Gallery was being seriously considered, and hoped that ere long they would have buildings to serve these purposes worthy of the Metropolis of the North.

As to the future home of their association he offered £500 if the members would raise £500, or £1,000 if they would raise £1,000, before the close of this century, or he was willing to leave the offer open until the end of his presidential year, *i.e.*, March, 1901. By this means they would soon be able to erect a building worthy of their association.

In 1851 he heard Lord Brougham's address to the students of the London University. In the course of his address he remarked: "There is a movement in London to reduce the hours of labour. If it can be done do it. If you can increase wages do it. They are the movers and not the holders of capital, but you must teach them this lesson, that they must try to reduce the cost of home products at the same time, and when by the reduction of their hours or increase of wages you bring in foreign competition, the movement must be stopped. Political economy should be to-night in all your schools. I do not know one in which it is to-night." Lord Brougham's remarks would be appropriate to-day; this question should be seriously considered by our Education Board: technical education, political economy, and striving to produce should be some of the main lessons inculcated.

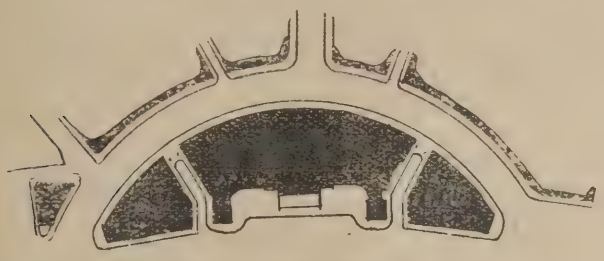
At the conclusion of his address, the President gave the following interesting statement, supplied by Mr. Laws, City Engineer, Newcastle, and Mr. Bower, Borough Surveyor, Gateshead:—Within the boundaries of the city of Newcastle there have been built during the last twenty years 3,614 self-contained houses (including villas) and 6,910 flats, making the total number of houses erected 10,524. Within the borough boundaries of Gateshead during the last twenty-five years 720 acres have been laid out for building purposes, 158 superior self-contained houses (including villas), 875 workmen's self-contained and 2,650 flats have been erected, and 130 flats are now in course of erection. The following notes on Gateshead from Mr. L. H. Armour are also interesting:—From the information I have I estimate there are about 800 acres of land within the three miles radius of the Monument laid out for building purposes, but not yet built upon. Assume 20 flats per acre on this area, you have 16,000 houses and 32,000 tenements, at an average of five per house, giving accommodation to 160,000.

A Stained-Glass Window at Compton Greenfield Church, executed by Messrs. Burlison and Grylls, of London, was dedicated recently. The window has been erected just over the pulpit, and the subject is St. Timothy of Ephesus. The window is the first of a series of seven to be erected at some future time with figures illustrating the seven churches of Asia.

Bricks and Mortar.

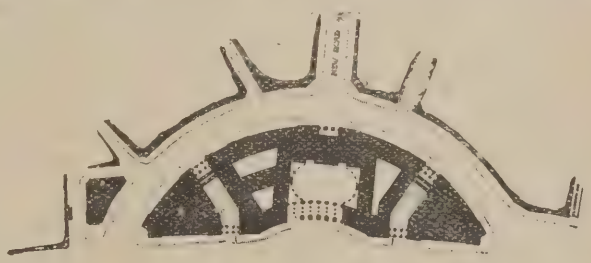
APHORISM FOR THE WEEK.

He that hath a house to put his head in, has a good head-piece.—SHAKESPEARE (King Lear, III. 2).



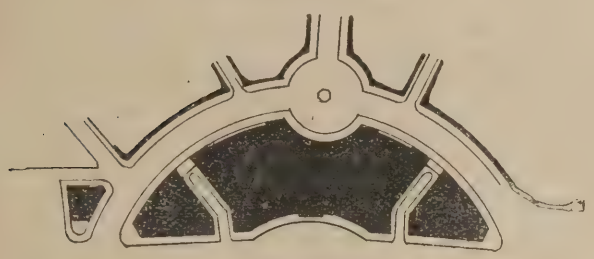
Our Plates. WE give this week elevations and plans of designs Nos. 17, 19, 20 and 21 in connection with the new street from Holborn to the Strand. A criticism of these designs appeared in our issue for October 31st last.

Dilapidations. DEAN TRISTRAM, of Durham, is of opinion that there is no need for the proposed new Dilapidation Bills; what is needed is some slight amendment of the existing law and some modification of its application. He says that the hardships under its present working arise largely from preventible causes. If the clergy universally availed themselves of its provisions and had a quinquennial survey, the cost would be comparatively trifling, and they or their executors would have nothing to pay at the avoidance of the benefice. But, forgetting that "a stitch in time saves nine," too many incumbents think "it will last my time," and thus leave a yearly increasing burden on their heirs. "Let the quinquennial survey be compulsory on all. There needs some check on the caprice of diocesan surveyors. The present check is illusory. The diocesan surveyors have formed what is practically a trade union, and hold together, having agreed on certain rules. I could adduce many cases in which no allowance is made for natural wear and tear, as the refacing of stones weathered by time in a perfectly sound wall. In one case where an ancient weathered garden wall contained a remarkable collection of rare ferns the surveyor insisted on its being stripped and pointed. In another an ornamental battlement, quite needless to the house, had the tracery of its mouldings decayed by time, and the outgoing incumbent was compelled to replace all the partially worn stones at a cost of £100, against the wishes of his successor."

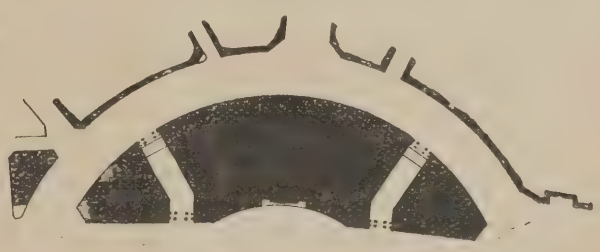


The Dean's Own Case. "AGAIN, the intervention of the officials of Q.A.B. with their red tape is useless and irritating, and often unjust. In my own case I had built a vicarage at my own cost, without encumbering the benefice. My architect, who happened to be the diocesan surveyor, advised me not to go to the expense of a survey for a few years, as there could be no dilapidations on the new house. Three years passed, then came another surveyor; I was unexpectedly promoted, and to my surprise was charged £156 for dilapidations. I took the surveyor's report to a builder, taking good care he should not know the amount of the estimate. He did the work for £119, and I got the surveyor's certificate. On applying to Q.A.B. for the balance, £37, they declined to refund it, saying that I must abide by the estimate, not the actual cost. They declined to state what they would do with the money. I consequently took counsel with my successor, and he built a wall, and I think a poultry-house, and so extracted the balance from the maw of Q.A.B. But I was defrauded all the same. Let the principle of the five years' survey remain; but in cases of dispute let the matter be referred to arbiters nominated by each of the parties interested, without the intervention of the officials of the Bounty Office, and the clergy would be satisfied."

A London of Flats. THE average flat, said Mr. Leonard T. Snell at last Wednesday's meeting of the Auctioneers' Institute, erected any time within the last few years, was in every way a considerable improvement on its predecessors. Both arrangement and design still left much to be desired; but, looking to the restricted areas upon which these buildings had to be erected—owing to the abnormal price of land—this standard was as high as could be expected. The rooms of modern flats were high, lofty, airy, and of good size; their sanitary fittings were of the best type; their drainage system was beyond suspicion; and their general finish and structure were superior to houses of rental value equal to the most expensive of flats. The flats system was, in fact, the only one possible or desirable in London and other great towns where land was dear and scarce, and where the population was so rapidly increasing. The lecturer went on to deal with the class of building which is a combination of flat and hotel. He could see an immense fortune for flats; and at the present time there were thousands of people ready to live in them. He was prepared to support the theory that a £200 a year flat was cheaper than a £100 a year house. With an ever-increasing housing problem they must have full utilisation of available areas. There must be a limit to the boundaries of a town, and the congested state of traffic was largely due to the immense area London occupied. "Twopenny tubes" were, after all, merely palliatives. What they really wanted was the concentration of the workers within a reasonable distance of their work, and that could only be done by means of buildings erected on the flats principle. If the whole population of London was resident in flats its area could be reduced, say, one-third, and hundreds of thousands of workers could then live near their work. The idea of a trim little villa or cottage in the country or suburbs was very pretty and idyllic, but the daily journey on a suburban line or a jolting omnibus soon knocked the romance on the head.



Art Education. FRENCH art received a high tribute of praise last week from Lord Reay when opening an exhibition in the Medical Examination Hall on the Victoria Embankment, of drawing, colour work, modelling, woodwork, wood carving, and metal work executed in day and evening continuation schools of the School Board for London. The primary object of the exhibition was to enable teachers to compare the results of various systems of teaching, with a view to the adoption of sound and true methods. M. Constant, the well-known French artist, was present. He had painted a portrait of the Queen, said Lord Reay, which would give to future generations as admirable a representation of her Majesty as could be desired. They were aware that the best education in art was given in France, and in this exhibition would be found abundant evidence of the influence of the French methods. He should like M. Constant to tell his countrymen that they had returned from the Great Exhibition on the banks of the Seine with a deep sense of the quality and refinement of French art. They warmly appreciated the prizes the Board obtained at the Exhibition, and were pleased to have received an invitation to a place in the International Educational Museum which it was proposed to establish in Paris. Such museums would tend to make them realise that in this great work of education nations could stimulate and assist one another in lifting the burden of ignorance which was the chief cause of misunderstandings between nations that had everything to gain by having harmonious relations. Lord Reay then gave a description of the exhibition, and said that the pieces sent in showed a marked improvement all round. Earl Beauchamp had, he added, asked for exhibits to be sent to New South Wales, and the Board were going to comply with the request. A report had been received from an architect connected with the German Government in which he highly praised their educational system, and had stated that they were making art education in London play the same part in their civilisation as music did in Germany. They would have great pleasure in exporting to Germany objects from this exhibition labelled "Made in London Schools."



PLAN OF DESIGN NO. 17.

PLAN OF DESIGN NO. 19.

PLAN OF DESIGN NO. 20.

PLAN OF DESIGN NO. 21.

HOLBORN TO STRAND THOROUGHFARE.

Leamington Parish Church has been enlarged and improved. The church is only about 60 years old, and it is said that it was designed by the then vicar. The extension, which includes the addition of two bays to the nave and a new baptistery, was designed by the late Sir Arthur Blomfield, and has been carried out under the supervision of his son. A western tower also forms a feature in the design, but its erection is postponed until the necessary funds are obtained. The school children have provided a new font for the baptistery. The improvement will cost eventually nearly £20,000.

SETTING-OUT WORK AND BUILDING BY-LAWS.*

BY J. BARTLETT, M.S.A.

THE subject of this paper is so large that I feel I cannot in the time allotted deal fully with the whole of its branches, and I therefore propose to deal with the first part more fully than the last, and, as to the numerous by-laws, to indicate the several parts and sections of the various Acts relating to building with which it is necessary you should be fully acquainted. These sections and parts you can easily refer to in print, and thus obtain a fuller knowledge of this subject.

Interpretation of Drawings to Scale.

It is an old rule that the fittest survive, and so it is with the scales adopted for plans. Plans to scale are broadly divided into two classes:—(1) Surveys dealing with land, roads, drainage, and railways; (2) Working plans and details dealing with building and engineering.

As regards the first division (surveys), the principal scales used are such as will work in unison with those adopted by the Ordnance Survey, the small scale plan of which is to a scale of 208·33ft. to the inch, or 25·344in. to a mile; the large scale being 88ft. to the inch, or 5ft. to a mile. As a large portion of a survey is made by means of a Gunter's chain, which contains 100 links and equals 66ft., and eighty such chains equal a mile lineal (5,280ft.), we find that the scales adopted for surveys differ considerably from those used for building plans, and thus we have for survey plans scales which are divisible by chains; such as two chains, or 132ft. to one inch; one chain, or 66ft. to one inch; and one-third chain, or 22ft. to one inch.

There can be no hard and fast rule against the adoption of any scale for any particular purpose, but as a survey plan has often to be compared with the Ordnance record it is advisable to prepare it in such a scale as will expedite the reference.

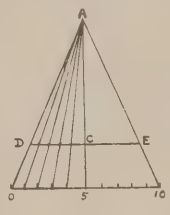
Owing to the small scale to which surveys are drawn, it has been found necessary to use certain recognised signs to denote the presence of various details.

(A large scale drawing showing the various signs used was fully explained to the audience, and several survey maps of London dating from 1540 were compared with those of the present day.)

In the preparation of plans for railways, sewers, or roadmaking, it is a rule that the sections shall be drawn to two scales, the longitudinal scale agreeing with that to which the plan is drawn, while the vertical one is usually drawn to a scale of 10ft. to 1in. The section is figured up from a datum line which is usually made to agree with the datum on the Ordnance (given alike in decimals).

The enlarged vertical scale gives an erroneous impression as to the fall of the sewer and road, &c., but it makes clear the points on the section at which the inclinations differ, while if the section were shown to the one scale horizontally and vertically these points would be quite unrecognisable.

(A large scale section was worked out for a proposed road and sewer in order to explain its construction.)



Passing to the general building plans with which you will no doubt have more to do than with survey plans, we find that for general building purposes the scales mostly used are in contract plans, sections, and elevations either a scale of 8ft. to 1in. or 4ft. to 1in., while for details we have as a general detail $\frac{3}{4}$in. to a foot and 1in. to a foot. These scales have been found to best meet the several requirements, and are most generally used in practice. With the $\frac{1}{2}$in. scale, which is mostly in use, it is not possible to show the internal finishing of the building to the extent of the $\frac{1}{4}$in. scale, but we have for these purposes the specification and the enlarged details to supply the information required. Every set of plans should have a sufficiency of sections.

The War Office adopt as general scales for building plans the scales of $\frac{1}{8}$in. and $\frac{1}{16}$in. to a foot. These scales are very small and do not allow so much detail to be shown as the $\frac{1}{8}$in. and $\frac{1}{4}$in. scales adopted by the profession outside their influence.

With the great strides lately taken by photography and lithography you may find it necessary to produce a scale by which to read plans prepared by these processes. In the case of photography, with a knowledge of perspective drawing it will be possible for you to find the centre of vision and produce some object in the picture to the edge of the picture plane and thus obtain a definite measurement. Or the presence of brickwork will enable you, by counting the courses, to obtain the heights and lengths.

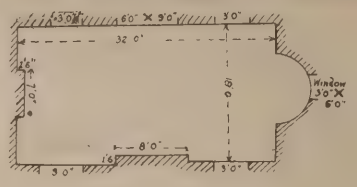
In the case of plans reduced by lithography the scale may be arrived at by reducing in the same way as you can produce a $\frac{1}{16}$in. scale from a $\frac{1}{8}$in. The most accurate method is as follows:—

Set up to any scale larger than the plan to be dealt with a length of, say, 10ft., shown on the accompanying illustration as 0 to 10. At right angles to this from its centre produce a line to any point A; join A to 0 and 10. Take from the litho plan for which the scale has to be prepared the length of any portion which should scale 10ft. Divide it into two equal parts, and from the line A 5 at C erect the parts at right angles to A 5, so that the distance D E is equal to the 10ft. on plan. Produce from the points 1 to 10 respectively lines to the point A, cutting the line D E, which is now equally divided and can be increased to prepare the scale required.

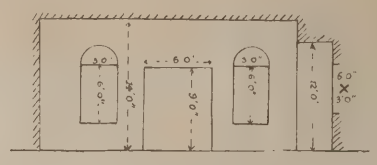
Next, your scale, if of feet, should have a section of 10 at the left-hand side divided up to assist in measuring uneven lengths, or when the scale is a building one and is dealing with feet and inches it should have a similar length, namely 1ft. with the division of inches.

A word or two as to the colouring of plans. Drawings should show by their grades of colour the several parts that are in section, plan, or elevation. The tints should graduate alike as regards density of colour, work in section being darkest; plan or horizontal section a tone lighter; elevation very light. It is misleading on small-scale plans (as $\frac{1}{8}$in. and $\frac{1}{4}$in.) to make distinction of colours in woodwork for one wood as against another. Drawings of old work should be shown in black to the walls, but the floors should not be coloured.

Calculation of Areas and Cubic Space.



We will now take a simple example and work out:—(1) area of floor; (2) area of straight walls without windows; (3) area of circular walls; (4) cube of room.



Area of floor:—

Ft. in.		
32·0

In the setting-out of works it is essential that proper projection be left on the several walls for the footings. Where works are set out on vacant land it becomes necessary to have a good square.

Next be careful to level up to some recognised point as the ground-floor level, and fix it in some convenient point or points from which the level may be checked. It is advisable to have a second point, as when the building is kept waiting for stonework the work is often carried up, and so the levels are inaccurate.

A storey rod should be kept and on it should be marked, on one side, the main projections, sills, cornices, &c., while on the other should be the courses of brickwork. In laying the concrete for the trenches the level of the top should be indicated with pegs carefully levelled. The footings are often a source of trouble, owing to the bricks being rougher, and so putting levels out. The position of the top of the damp course should be marked on the storey rod, and no work should be allowed to proceed beyond that level until it has been thoroughly checked as to its levels. In large works a dumpy level on tripod is used, but in ordinary works the straight-edge and hand level are sufficient. A good foreman when upon the works will readily detect any work out of the perpendicular or laid to improper levels, as when the building is in carcase nothing is easier than to range the lines of brickwork with timbers, and the lines of one opening with another.

I will now pass on to the Acts of Parliament and by-laws, and point out to you the special sections to be studied.

Take first the

London Building Act of 1894.

Part 1, Introduction.—The forty-seven definitions of the various expressions used in this Act should be mastered, although it will be

* Paper read at the Carpenters' Hall, London, on November 1st, 1900.

found that the terms "building" and "structure" are not included in the definitions. Parts 2, 3 and 4, relating respectively to formation of streets, lines of building frontages, and naming and numbering of streets, may be passed over. Part 5, Section 40, dealing with light and ventilation of habitable basements, and Section 41, as to the space at rear of domestic buildings, should both be studied.

Section 43 gives permission to cover old sites under certain regulations as to the plans of the existing buildings being certified by the district surveyor, but this section is in turn varied by the regulations of the by-laws of the London County Council and district by-laws when water-closets exist on areas almost entirely covered. Sections 47 and 48 relate to the height of buildings. The principal part is Part 6. Here, from Section 53 to 81 inclusive, the whole deals with the construction of buildings.

It may be well to mention here that the proposed building regulations code now under consideration by the Municipal Assembly of New York sets forth with regard to foundations that when no actual test is demanded the sustaining powers of various soils are to be taken as follows:—Soft clay, one ton per square foot; ordinary clay and sand, wet and springing, two tons; loam, clay, and fine sand, firm and dry, three tons; very firm coarse sand, stiff gravel, and hard clay, four tons. In cases where testing is required, it is stipulated that the Commissioner of Buildings shall be represented, and that a record of the results shall be duly lodged in the departmental offices. Intensity of pressure under footings is to be regulated in accordance with modern practice relative to live loads, and the footings must be designed so as to distribute the load equally and to prevent the establishment of pressure exceeding the safe bearing capacity of the soil, as previously set forth. Factors of safety, unit stresses for wooden and metallic columns, and wind pressures are all dealt with in a manner according with recent engineering practice. Safe loads on brickwork are now fixed at eight tons in the case of Portland cement-mortar. The strength of concrete variously proportioned is duly stated, and there are sections bearing upon the properties of stone, brick, sand, lime, cement, &c., fireproofing, and encasement of girders and pillars.

But to return to the London Act. The first and second schedules should be carefully studied, as they deal with the actual materials, their quality, and the manner in which the work should be constructed, the second schedule setting forth very fully the various materials that will be accepted as fire-resisting materials under Section 74, Part 6, and others where parts of a building are required to be in fire-resisting materials.

Next we have the unrepealed parts of various Acts, and so we come to the Metropolis Management Act, 1855 (18 and 19 Vict.), which, in Sections 73, 74, 75, 76, and 77, deals with drainage, in Section 82 authorises the inspection of private drains by the inspectors of vestries and district boards, and in Section 85 gives authority for the vestry to do the work. Sections 101 and 102 deal with the construction of vaults under footways.

Next, the Public Health Act (London), 1891, Sections 93 and 97. Section 96 deals with underground rooms for occupation, the construction of such rooms to prevent damp, the paving of the areas from which lighted, the drainage of the area and soil under the room, the lighting and ventilation, &c.; while Section 97 is devoted to regulations as to the supervision of and closing of such rooms.

Next we have the by-laws of the County Council under Section 16 of the Metropolis Management and Building Acts (October 19th, 1891). Here, under Sections 2 and 3 respectively, we find requirements as to the foundations and sites of buildings, and description and quality of the substances that may be used for walls. Amongst other items we find the requirements that stone must be laid on its natural bed. Under the same by-laws we have special provisions dealing with the description and quality of the substances of which plastering is to be made, and a further important provision dealing with the method in which any excavation around the site and the building is to be filled up.

Another set of important by-laws of the London County Council is that dated June 22nd, 1893, dealing with the construction of water and earth closets. These by-laws deal very fully with the various details, such as pans, traps, weight of pipes, soil pipes, water supply, ventilation, &c., and in addition, under clauses 16 to 19, both inclusive, they deal with the construction of ashpits and receptacles for dung as attached to stables.

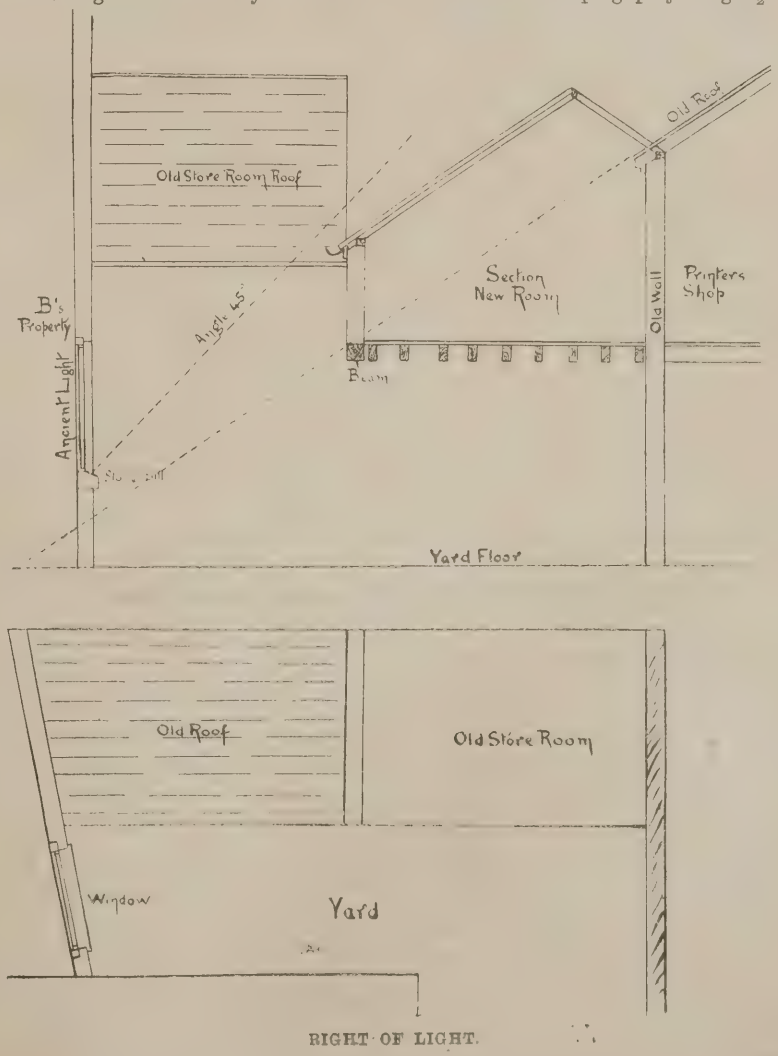
The by-laws of the several districts round London contain the various requirements as to building materials and sanitation to which I have directed your attention in the Metropolis Management Act, and the Public Health Act, and the by-laws of the London County Council, and by studying the several parts of the Acts which I have named this evening you will obtain a knowledge of the principal requirements of the several Acts of Parliament relating to buildings as affecting their construction and sanitation.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Edit . The querist's name and address must always be given, not necessarily for publication.

Ancient Lights.

KIDDERMINSTER.—PUZZLED writes: "A is altering his premises as shown on the accompanying sketch. B is the owner of the adjoining premises, and objects to A proceeding with the work on account of his ancient light. The proposed building will be well within an angle of 45 deg. Has B a right (he claims it) to the line of light as shown by the dotted line? If not, say what is his right. Do you know of a good book on this subject?"



Draw a straight line from B's window sill to touch the highest salient point of the old roof opposite. Anything raised above this line would be an infringement of B's right of light. The angle of 45 deg. does not limit his right, though it might form the basis of a reasonable arrangement. A good book is Roscoe's "Digest of the Law of Light" (London: Reeves & Turner, Carey Street, W.C.).

G. H. B.

Garden Walls.

BECKENHAM.—ENQUIRER writes: "In 'Specification,' under 'Gardener,' it is stated that garden walls should go 3ft. below the surface of the ground. Kindly say if 20in., including 6in. of concrete, will be sufficient for a 9in. wall 6ft. or 7ft. high (from the surface of ground), with piers 14in. by 4½in. on the inside only. Will 9ft. in the clear be a sufficient distance apart for the piers so as to allow for training fruit trees? Is a damp course necessary? The wall will point north-west. Do you consider the above dimensions sufficient, or more than sufficient, for a perpendicular wall 700ft. long on clay soil? In building a house twelve miles from London, would it be cheaper and more satisfactory to buy timber from a local merchant or from the docks?"

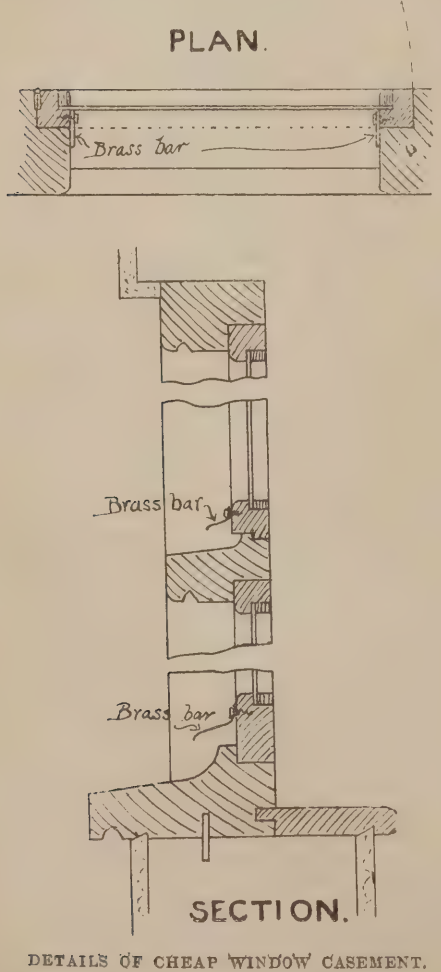
Garden walls should be built deep enough to allow 3 ft. of soil against them. A depth of 20in., including concrete, is not enough. A wall 9ft. high is much more serviceable than one 6ft. or 7ft. high; only dwarf-trained trees could be grown on the latter. The piers should not be placed on the inside (growing side) of the wall. Piers 14in. by 14½in. 9ft. apart would be satisfactory. Querist states that the wall points north-west. Presumably that means a south-east aspect for the trees on the wall, which is good for the southern part of England. A wall in the north should preferably face south. A damp course is not necessary. The wall should have a coping projecting 2½in. or 3in

RIGHT OF LIGHT.

A simple means of providing an additional temporary coping, which is useful in the spring and can be removed in summer, is obtained by building in the wall, under the coping, pieces of 1¼in. galvanised-iron tubing 2ft. long and about 6ft. apart, in which iron can be placed projecting 1ft. beyond the wall, being kept in place by a pin through the outer pipe. On these supports light boards 9in. or 12in. wide can be placed in the spring and retained there as long as necessary. Netting can also be suspended if it is required to protect fruit against frost, birds or wasps. Horizontal wires may be strained on the wall about 9in. apart. If the timber referred to is for hothouses it is preferable to buy it from a builder, as it will probably be more seasoned. A. E. M.

Amounts Chargeable by an Architect.

BRADFORD.—FAIR PLAY writes: "In making out a bill against a client, has the architect a right to include in the total cost of the buildings any amounts in excess of the P.C. sums allowed in the contract, which the client has expended but settled privately? Also, when a client requests that certain (say painting) work need not be advertised, as he intends to give it to a firm with whom he bargains and pays privately, has not the architect a right to know what the cost has been, in order that he may include it in the total cost? There appears to be a legal understanding that the architect can only charge an amount certified, irrespective of time given in consultation and information supplied with regard to external finishings and decoration."



It does not appear that an architect could charge by percentage on the cost of such works, but he might charge for time spent in consultation upon them with his client.

G. H. B.

Cheap Wooden Casements.

F. R. writes: "I should be glad to have some details of a cheap wooden casement."

The accompanying sketch will no doubt meet querist's requirements. R. W. C.

DETAILS OF CHEAP WINDOW CASEMENT.

L.C.C. Scholarships.

LONDON, W.—ROBERTS writes: "I intend to prepare some drawings for the L.C.C. scholarships in building construction. What subjects would you advise me to draw? Who publishes, and what is the price of, Roger Smith's book on the orders? Do you think there is enough in Mitchell's book on advanced building construction for a student studying for honours, South Kensington?"

It would be well to make as many sheets of drawings as possible of constructional work on good paper (such as Whatman's), each properly inked in and coloured. Thus, one sheet might comprise details of a staircase, another of a dormer window, another of an iron roof, and another of some fireproof flooring. These might be copied from such a compilation as Mitchell's "Sheets" (obtainable from the Polytechnic, Regent Street, W.), but would be better if measured from actual examples, this fact being stated. Mitchell's "Advanced Building Construction," though an excellent book, should certainly be supplemented by several others while reading for S.K Honours, it being never wise to trust to a single book on any subject. Professor Roger Smith's "History of Architecture," if still in print, can be obtained from Mr. B. T. Batsford, 94 High Holborn, W.C. G. A. T. M.

The Title "Architect."

CRAWLEY.—A WOULD-BE ARCHITECT writes: "Having served my pupilage, passed first-class in building construction (advanced and elementary), and started a practice in a country village, is it permissible to put 'Architect' on my cards and office plate?"

Anyone may put "Architect" after his name, whether he is qualified or not. This is why there is such a clamouring for legal registration.

Colour Schemes.

GALLATOWN.—HARMONY writes: "I should be glad to know of a good illustrated book on colour, so that one could judge of various shades and their combinations, such as 'picking out' cornices to match wallpapers."

No book will help queriest unless he possesses a natural talent for arranging colour schemes. We would recommend to him the articles on 'Decoration and Furnishing" which appeared in our issues for September 5th and 19th last.

What is "Gesso"?

BARNSLEY.—PERSEVERANCE writes: "Will you kindly give information about 'Gesso' work; what it is, how it is done, and what are the materials required?"

An article on Gesso appeared in our issue for June 6th, 1900.

Registration of Architects.

SOUTH SHIELDS.—A. B. writes: "If the Architects' Registration Bill is passed, how will it affect young architects who have completed articles and have commenced a practice, or secured a partnership, though not members of the R.I.B.A?"

Under the Architects' Registration Bill nobody would be allowed to practice as an "architect" unless he had passed the examinations which would be instituted by the Bill. A roll would be formed of the names of all those persons calling themselves architects at the time of the passing of the measure; all would be included, bogus and real alike. We therefore presume that a young architect just commencing to practice would have just as much right to be included on the roll, when first drawn up, as the oldest member of the profession.

Skittle Alleys.

AYR.—J. K H. writes: "Can you give me any information regarding the details of construction of a skittle alley, including the length and width required for a double alley? Are there any books published which give such information?"

We know of no book on the subject. Particulars were given in our issues for February 21st and June 13th, 1900.

Books on Gothic Architecture.

LONDON, W.—A. J. writes: "Can you give me the names of some good books on Gothic architecture which would be of service to a student? Details and construction are required more than reading matter."

"Details of Gothic Architecture," measured and drawn by J. K. Colling, £2 2s. nett; "History of Gothic Art in England," by Edward S. Prior, M.A., £1 11s. 6d. nett; or "Gothic Architecture," by H. E. Corroyer, 5s. These can be obtained from Mr. B. T. Batsford, of 94 High Holborn, W.C.

Shop Fronts.

HINCKLEY.—MAC writes: "Is there any book published on shop fronts and windows?"

We know of no book on the subject; illustrated articles on "Shop Fronts" appeared in our issues for August 9th and 16th, 1899.

THE SEVENTEENTH-CENTURY ARCHITECTS.

AT last week's meeting of the Bristol Society of Architects, Mr. Joseph Wood, vice-president, in the chair, Mr. Harold Smith, A.R.I.B.A., lecturer on architecture at the Merchant Venturers' College, delivered an address on "The Architects of the Court and Capital of England in the Seventeenth Century." The speaker first dealt with the renaissance of the Elizabethan and Jacobean periods, showing how it eventually culminated under the patronage of the Court in the work of Inigo Jones. He then spoke of the effect of the civil war, and pointed out that most of the artists of the Restoration were foreigners. After a description of the capital as it was in the seventeenth century, the speaker concluded by describing the work of Sir Christopher Wren in restoring the city, building St. Paul's, and adding to Hampton Court and Greenwich Hospital. The paper was illustrated by numerous fine photographs, shown by means of the lantern, and also an interesting collection of prints relating to work of the period.

INCORPORATED INSTITUTE OF BRITISH DECORATORS.

IN connection with the proposed visit of the members of this institute to Italy early in the new year, a paper was read on Thursday last at the Painters' Hall, Little Trinity Lane, London, E.C., by Mr. Thomas Preston on "Italian and Decorative Art." The chair was taken by Mr. J. D. Crace (president). Mr. Preston, in the course of some opening remarks, gave an outline of the proposed trip. Speaking of the 200 years between 1380 and 1580, when the great Italian painters were at work revolutionising art, reminded him that Cimabue, Giotto, and others escaped gradually from the fixed symbols and dead traditions of early Christian art. Nature was seen more truly by them and represented in relief. At the command of the Church these men produced pictures on the walls of various churches in fresco—the prepared colour being laid on the wet plaster. Afterwards altar and panel pictures were done in distemper, while, in the later days, oil became the medium for easel and other pictures. Views of a number of the principal works of art in Rome, Florence, and other Italian cities were thrown on a screen, being accompanied in each case by descriptive remarks by the lecturer. A discussion followed.

A New Board School at Streatham at Sunnyhill Road has been opened.

Workmen's Dwellings for Brentwood.—The Brentwood Urban Council have decided to purchase for £2 per foot frontage a plot of land in Western Road as a building site) subject to the sanction of the Local Government Board), for workmen's dwellings. The site has a frontage of 450ft., and a depth sufficient to provide gardens. There is room on it for the erection of 33 houses. The total estimated cost of carrying out the scheme is £6,500

Professional Practice.

Barrow.—The new Emmanuel Congregational Church was opened recently. The church is built on a fine sight, situated at the corner of Ainslie Street and the Abbey Road. The total length of the building is 92 feet, and the width between the transepts 58 feet. The main entrance, approached from the Abbey Road, is placed in the centre of the building, having on one side a cloak-room, and on the other (off Ainslie Street) an additional entrance leading to the gallery, which is placed over the front vestibule. The church is planned to seat 550, and the seats, as also other woodwork of the church, are in pitchpine. The open roof, although not costly, is nevertheless ecclesiastical in appearance, and looks very effective. The walls inside up to a height of five feet are built with best red facing bricks with ornamented friezes, and above in plaster. The choir seats are placed right and left of the pulpit, and the recess behind will eventually be filled with an organ. The building is designed in the Gothic style of the perpendicular period. The materials are of limestone from the locality, and the tracery of windows and other dressings of the St. Bees red stone. The roofing is of green slates. The building is lighted throughout with the electric light, put in by Messrs. Thornton and Son, of Barrow. The contractors are: For stonework, Mr. W. Fairbairn; bricklaying, slating, and plastering, Mr. J. H. Neal; carpentry and joinery, Messrs. W. Gradwell & Co.; plumbing, glazing, and painting, Mr. Morris. The church was designed for a tower and spire, but this portion had to be abandoned. Mr. E. M. Young is the architect.

Belchford.—The church of SS. Peter and Paul at Belchford has been reopened after restoration. The church was rebuilt in 1871 in the characteristic poor style of that period. Some years ago it became almost unsafe, and the walls were strengthened to prevent their falling. The chancel was rebuilt in 1859-60, and in 1884-5 the church was re-seated, the plaster ceiling removed, a new floor supplied, and fresh windows inserted. However, such was the all-round bad structure of the building, that but few years had elapsed before signs of decay showed themselves in an alarming fashion. The architect for the scheme of restoration was Mr. H. M. Townsend, of Peterborough, and the major portion of the work has been executed by Messrs. Thompson, also of Peterborough, who carried out the work of restoring Peterborough Cathedral and the Chapter House, Lincoln. The tower, which was unsafe, has been pulled down, portions only of the walls being retained as were sufficient to form the sides of a plain porch at the main entrance to the church. This porch is, however, only of a temporary character, it being the intention, at no distant date, to rebuild the tower in a style suitable to the building as a whole. While some of the old stones of the tower—a collection of masonry work of different church periods—have been piled up at the far side of the churchyard, others have been used in the building of a new vestry, which opens into the church, and can also be used as an organ chamber. Five good-sized windows, decorated with tracery work, and giving good light, have been let into the walls of the church; and the whole of the outside of the remainder of the building has been repointed and put into a thorough state of repair. The chancel contract was given to Mr. J. W. Jackson, of Lincoln, and this and the walls of the body of the church have been decorated by Mr. Travis, of Owstown Ferry. The walls of the chancel are darkened with terra cotta and green colours, of the seventeenth-century period, and the roof has been treated with black and white arrowhead work. The choir stalls are stained green, and decorated in harmony with the wall of the chancel. At the end of each stall is affixed a shield bearing the arms of Saints Peter and Paul. The old altar has been placed in the south-east corner of the church to serve as a side altar, and a new high altar of oak, gilt with five painted panels on a gold ground, supplied by Mr. L. Grosse, of Belgium, stands in its place. The old round-headed arch of the chancel put up in 1780, when the church was rebuilt, has been replaced by a newer one. The interior walls of the body of the church have been renovated. For the present chairs will be provided as seating accommodation in the nave, though it is hoped that benches will be provided ere long. The whole of the church is heated on the American radiator system, supplied and fitted by Messrs. Ward and Co., Horncastle. The heat is generated from a boiler in a heating chamber underneath the vestry, which is entered from outside the church. The radiators are of the flue kind, formed on the Italian principle. In the nave there are four radiators, in the chancel there are two, and in the vestry one. Any one or all the radiators can be used at one time, and in addition the heat can be regulated to any degree. In the porch of the church is an old stoup that formerly belonged to the church, but eventually found its way into the yard of the house of the churchwarden, from whom it has been reclaimed. One discovery made during the restoration was the foundation of a wider church which formerly stood on the spot. There are evident signs, too, that when the old church was pulled down it was hastily put up again, for amongst the unused stones taken down during the restoration are bits of masonry of various church-building periods, which in the re-construction process in 1780, were put in the most unlikely places. The portion of the foundation and other portions of the old church have been covered over again. The work of restoration has been well carried out under the personal supervision of Mr. Hopkins, foreman to Messrs. Thompson, builders.

Burton-on-Trent.—New premises which have been erected in Byrkley Street by the Burton-on-Trent Co-operative Society, Limited, at a cost of between £8,000 and £9,000, were opened on the 15th inst. by the President, Mr. S. Redfern. The building is English Renaissance in style, and stands on a site previously occupied by shops and cottages, having a frontage of 79ft., with a depth of 70ft. Great difficulty has been experienced during the progress of the work by the necessity for keeping open three departments of the business, and an entrance for the traffic to the stores, bakehouse, &c., which are situated in the rear of the new premises, and only accessible across the site. The premises have a basement, 76ft. by 38ft. with a strong room, coal stores, and a heating chamber. On the ground floor are four lofty shops, with out-offices, &c., for the grocery and provision, drapery, boot and shoe, clothing and outfitting, and butchers' departments. In the centre is a large covered entrance for access to the society's other premises in the rear, and from which also rises the main staircase to the upper floors. On the first floor are a large show-room, a board room and managers' and general offices, with the necessary lavatory accommodation. On the second floor is a concert hall, 76ft. by 39ft., seating 500 persons, with platform and two retiring rooms. The ceiling is covered and panelled with moulded and enriched plaster ribs, and the front of the proscenium is executed in elaborate modelled fibrous plaster, the windows being of leaded lights specially designed in the studios of Messrs. Pearce, Limited, of Birmingham. Provision is made for ventilation by means of tubes and exhaust ventilators in the roof. The building is fireproof throughout, being built with steel stanchions and girders suitably cased and protected. The floors and staircases are of concrete, and, together with the stanchions and girders, were executed by Messrs. Lindsay and Co., Limited, of Westminster, in their patent system, the floors being finished with wood blocks by Messrs. Ward and Co., of Westminster. The heating is on the low-pressure hot water system by pipes and radiators, executed, with the ventilation, by Messrs. John King, Limited, of Liverpool. The lighting is by electricity, the installation being by Messrs. Gardner Brothers, of Burton-on-Trent, the current being supplied by the Corporation. A service of gas is also laid for emergencies. A very complete system of fire appliances has been fitted by Messrs. Merryweather and Sons, of London. Messrs. T. Lowe and Sons, of Burton-on-Trent, carried out the general contract, and the plans were prepared by Mr. R. Stevenson, architect, Imperial Chambers, Burton-on-Trent, under whose personal superintendence the whole of the work has been carried out.

Caerwent.—The ancient church of Caerwent having undergone important works of reparation, begun in 1893, was reopened recently. This is one of the earliest and most interesting of parish churches in Monmouthshire. Caerwent ("The Fortress on the Wye"), the ancient capital of South Wales, once a seaport, was taken by the Romans in the days of Claudius Cæsar, and became the first Roman station on the western side of the Severn. The church now consists of an unusually long chancel dating from the thirteenth century, a nave with its fifteenth-century north porch and parvise, and fine fifteenth-century tower. Perhaps the most interesting features of the church are the two blocked or filled-in arcades on the south side, beyond which were once aisles, or more probably side chapels, of which only the foundations and a fragment of walling still remain. The south nave wall with its arches had gradually fallen outwards to the extent of some 18in., causing the building to be in a very dangerous condition, which necessitated the taking down and rebuilding of this portion of the fabric. It appears that the mediæval builders, although making use of the Roman building material at hand, did not take the trouble to build from the Roman foundations, some 5ft. or 6ft. deep, and had it not been for three huge stone props, built up in all probability when the chapels were demolished or fell in, the nave would have collapsed centuries ago. This wall with its arches has now been rebuilt on a secure foundation. The roof has been restored, and the nave thoroughly repaired by Mr. W. Clarke, of Llandaff, under the direction of Mr. G. E. Halliday, F.R.I.B.A., to whom the work of restoration was entrusted in 1893.

Harrogate.—The new building for the Yorkshire Home for Chronic and Incurable Diseases is now being erected on a site near Harlow Moor, Harrogate. The object of the institution is to provide "a home for chronic sufferers whose disease is pronounced incurable, and whose means are insufficient to secure to them the attention their helpless condition requires." The present home is situated in Low Harrogate, has been in existence 18 years, accommodates about 30 patients, and costs not far short of £1,000 a year to keep up. The new home will have about 50 beds, and there will be opportunity of extending the premises to meet the cases of 150 persons when requirements and means allow. Its cost is put at £15,000. The new building will have a frontage of 157ft. to Cornwall Road, and 85ft. to a side road. The ground floor accommodation comprises large day rooms for patients of both sexes (35 females and 15 males), dining-room, board-room, waiting-room, bath-rooms, and wards of varying sizes, and a winter garden. More wards and bath-rooms are planned for the first floor, together with nurses' rooms and asphalt airing flats opening into the corridors by wide doors. The kitchen, scullery, store, operating-room, isolation ward, and maids' rooms will be on the second floor, while the basement will contain the laundry and boiler house. Terazzo flooring and ventilation by means of an electrical fan, are other features. The elevations are to be neat and unpretentious, but not too conventional. Mr. T. E. Marshall, of Harrogate, is the architect, and Messrs. W. Nicholson and Co., of Leeds, are the principal contractors.

Histon, near Cambridge.—A "manse" is being erected in connection with the Baptist Church which was opened a few months ago. The manse is on land adjoining the church buildings, leaving room between for the future schools. The dining-room, drawing-room, study, cloak-room, kitchen, &c., are placed on the ground floor. Four bedrooms, dressing- and bath-rooms are placed on the first floor. A verandah and balcony carried on rustic woodwork forms a feature on the front elevation. The contract amounts to £780. Messrs. George Baines, F.R.I.B.A., and Reginald Palmer Baines

of 5 Clements Inn, Strand, London, W.C., are the architects for the complete scheme of church, schools and manse.

Kintore.—The rebuilding of the Station Hotel at Kintore, which has been in progress for over a year, has now been completed. The new building is of three storeys, with drying lofts, and has a frontage to the turnpike road. On the ground floor are situated the dining-room, coffee-room, bar, and private sitting-room; on the first floor is the commercial-room, drawing-room, and various bedrooms; while the second floor is entirely occupied by bedrooms. All the rooms have been decorated in bright colours. On the opposite side of the road, a recreation ground and a garden are to be laid out. The architect is Mr. John Cameron, Aberdeen, and the principal contractors were:—Mason—Mr. John Smith, Lilybank, Kintore; carpenter — Mr. John Maitland, Kintore; painter—Mr. Forrest, Holburn Street, Aberdeen; plasterer—Mr. Sievewright, Inverurie; slater—Mr. Farquhar, Woodside.

London, S.W.—The foundation stone of the new church of St. Anne, Vauxhall, was laid recently. The church is to have a total length of 140ft., and consist of a wide nave, 33ft. by 90ft., flanked by narrow processional aisles and transepts. The chancel will be 36ft. by 23ft., with two side chapels, together with sacristies. There will also be a large confraternity chapel, 33ft. by 18ft., with parish-room over it, parallel with the nave, opening by an arcade to the processional aisle. The style adopted is that of the thirteenth century, and the exterior of the building will be entirely of red brick. There will be accommodation for 700 people. Mr. F. A. Walters, F.S.A., is the architect, and the contractors are Messrs. Goddard and Sons, of Farnham and Dorking.

Weston-super-Mare.—The new front of the Government School of Science and Art was opened recently. The style of architecture is the Renaissance. The front has moulded cornices, sills, strings, copings, pediments, &c.; pilasters enriched with Faience panels, moulded bases, and elaborately-carved caps. The frieze of the entablature is also enriched with Faience panels. The spandrels of the arch to porch are carved. Two large bay windows give relief to the front, and the porch on the ground floor, only, gives a break in the vertical lines, the top forming a balcony. The gables of the building are ornamented with moulded and worked finials with balls and curved copings. The parapets have moulded balusters. The ground floor is built with local limestone, with freestone dressings, to give massiveness to the supporting storey. All above this is built of freestone with niches for sculpture, backed with good solid brickwork. The roof is covered with slates fastened with Harvey's system of screws and washers. The gutters and flats are of stout lead. The ground floor is laid with wood block flooring on cement-concrete. The first floor has massive steel girders with smaller steel joists between, having a fireproof floor of cement concrete, on which is laid wood block flooring. The second or top floor is formed with strong wood joists and flooring board. On the ground floor is a large hall 57ft 6in. by 17ft., and 15ft. high, having two bay windows, and this hall is entered by a porch. On the south or left-hand side of the hall is the staircase (lighted by windows) to the art schools arcaded towards the hall. Opposite the entrance doors to the hall are two arches (old). These archways lead to the science lecture room, trades technical classrooms, committee room, lavatories, and offices. The large hall, it may be stated, can be used as a permanent art gallery, or for exhibitions from time to time. On the first floor is a carving-room 28ft. 6in. by 17ft., and 12ft. high, having three windows. Next to this is the life-room, for studies from the life, 15ft. 6in. by 17ft. The master's room is on the north side, 17ft. by 12ft. Each of these rooms is 12ft. high. A corridor communicates with these rooms, and also with the present two large art rooms (elementary and advanced); also with the lavatories and offices. There is also a back staircase to this floor and to the top floor. On the second or top floor is a cookery classroom, 30ft. by 17ft. The latest cooking ranges will be fitted up in this room for lectures. Next to this is a scullery, also lavatory and offices. At the north and south ends of this floor are the caretaker's apartments. All these rooms are entered from the upper corridor. The first portion of the building was commenced in the year 1892, consisting of elementary room and advanced room, science lecture room, chemical laboratory, and three trade technical rooms, committee room, with cloak rooms, lavatories, &c. This contract was carried out by Messrs. Theo. Palmer and Son, under Messrs. Price and Wooler, the architects, at a cost of about £1,600. The second portion, completing the building, was carried out by Mr. Henry W. Pollard, builder and contractor, of Bridgwater, under Mr. Hans F. Price, architect, of Waterloo Street, at a cost of about £2,000. The carving was executed by Mr. J. P. Steele, of Kingsdown, Bristol.

Builders' Notes.

A Generous Gift.—Mr. James Carmichael, builder, of Wandsworth, has handed over to the Bolingbroke Hospital, Wandsworth Common, S.W., the nett proceeds of £150 15s. 10d. derived from the sale of seats at the Hôtel Cecil on the occasion of the return of the C.I.V. on October 29th last.

"A Discreditable Bankruptcy" — George Tuffley, 81 Earl Howe Street, Leicester, builder, lately carrying on business at Keythorpe Street, applied for his discharge at the Leicester Bankruptcy Court last week before His Honour Judge Wightman Wood. The Official Receiver said the receiving order was made in January, 1900, the liabilities ranking for dividend being £11,032 10s. 4d., and the proofs admitted for dividend being £10,460 4s. 2d. £3,964 were trade debts, and £7 076 due to the mortgagees, whose security was inadequate. The assets, estimated at £662 9s. 4d., only amounted to £485 15s. 6d., and a first and final dividend of 6½d. in the £ had been paid. Bankrupt had been a speculative builder, who had begun with a capital of £100 of his own, and £850 borrowed from relatives which had not been paid back. The Official Receiver submitted that this was a case where the minimum suspension of two years would not be adequate, having regard to the fact that it was a recent bankruptcy. His Honour said this was a very discreditable bankruptcy. Debtor had not kept proper books, and thus had kept himself wilfully in the dark as to his proper position. He had gone on getting extensive credit from people who had no information as to his position. Then he came gaily up after two months and asked for his discharge. He should suspend the discharge for four years from the date of the receiving order.

Export Duty on Austrian Timber.—An agitation recently entered upon by a number of influential industrial associations in Austria, having for its purpose the levy of an export duty on raw timber is reported by Mr. Hossfield, the United States Consul at Trieste. Under the existing commercial treaty between Austria and Germany, the rapid development of the latter has led to a change in the form of its timber imports. Formerly they consisted mainly of sawed lumber, railroad ties, staves, parquetry. The industrial associations in question now claim that since 1891, when the treaty was concluded, the export of these wares has become stationary, while the crude timber has increased 7,759,000 tons per annum to 15,139,000. They demand that measures shall be taken to restrict exportation in the crude form, and in order to promote this result they demand an increase in freight rates on timber intended for export; taxation of foreign timber merchants doing business in Austria; the enactment of stricter forestry laws; discrimination in favour of home industries in the sale of timber from Government forests; and, finally, that provision shall be made in future tariffs for reducing the export of crude timber, or an export duty upon it. An attempt will be made to have these protests heeded when the renewal is proposed upon its expiration next year of the present commercial treaty with Germany. The Consul expresses the opinion that, in any event, Germany will have to look elsewhere for sources of supply to meet the increasing demand for timber in her industries.

Cement in South Africa. — United States Consul-General J. G Stowe writes from Cape Town, September 17th:—"No country is a better customer for cement than South Africa. All public buildings, warehouses, stores, and residences are built of brick, cemented on the outside. No wood, or frame, houses are seen. The expert Malays, the masons in this country, are adepts in producing very pleasing effects with cement in the outside finish of buildings. The bricks used in South Africa are two-sevenths larger than the American bricks, and are laid up principally with "mud," the inferior clay found here, instead of mortar (lime) or cement. Over the whole surface cement is laid. Bricks of different shapes form the window sills, copes, columns, pilasters, mouldings, &c., and over these is spread the cement, forming a very pleasing exterior, the natural stone being closely imitated. Many of the large buildings are spattered with the cement, presenting a rough exterior very striking, and even durable. Cement is also used in making drainpipes, sidewalks, stoops, tiles, chimney-pots or tops. Brick exteriors are never seen, as the bricks are inferior, the best qualities being made of clay and coal cinders. Of the cement imports for 1899, amounting to 126,672,875lbs., Belgium furnished 18,423,628lbs.; Germany, 7,448 395lbs.; other countries, 605lbs; and the United Kingdom the balance. During 1900, the imports of cement from Germany have been increasing rapidly, as it has been found that German cement is equally as good as English Portland, and can be bought at 24c. per barrel cheaper. Belgian cement is good, and sells 36c. cheaper than the English. Cement of the desired quality will never be manufactured here, as the ingredients do not exist."

London County Council.—At last week's meeting of the Council, the Water Committee recommended that a Bill be promoted next Session for the purchase by the Council of the undertakings of the eight metropolitan water companies, and that it be referred to the Parliamentary Committee to prepare and present to the Council the necessary Bill for carrying out the above recommendation, and also the necessary Water (Finance) Bill. Mr. H P. Harris moved an amendment to give effect to the main principles of the report of the Royal Commission. Mr. Cohen, M.P., seconded the amendment, and said he recognised the defects of the trust proposed by the Commission. Sir Arthur Arnold said the proposed trust was so faulty that not a single county or authority concerned was satisfied. Liverpool had already solved the water problem upon the lines recommended by this Council. They were convinced that the only way out of the difficulty was purchase by the County Council. Mr. Shaw Lefevre said that nobody believed that the report of the Royal Commission could be carried out in its entirety; such a recommendation was impossible. In that case an alternative was necessary, and the Water Commission had suggested that alternative. He was prepared, after purchase, to agree to a compromise as to future management. On a division the amendment was defeated by 70 votes to 44. Mr. Campbell moved a further amendment to the effect that the Government be requested to bring in a Bill to carry out the recommendations of the Royal Commission, but this was lost on a show of hands, and on a division the adoption of the report was carried by 71 votes to 43. The Housing Committee reported that since March last dwellings costing £150,446 and accommodating 2,428 persons had been completed. Tenders received for the supply of arc lamps for the Victoria Embankment and Westminster Bridge were referred to the Highways Committee for report. Upon the recommendation of the Finance Committee, it was agreed to lend the Hampstead Guardians £2,005 for the erection and equipment of a boiler-house and the installation of electric light; and the Metropolitan Asylums Board £75,000 for the erection and fitting of an asylum at Tooting Bec.

Law Cases.

A Builder Fined for Laying Faulty Drains. At the Coalville Petty Sessions a builder named Hewes was recently summoned for unlawfully causing a drain from certain premises to empty itself into the sewer of the Coalville Urban District Council without complying with the provisions of section 21 of the Public Health Act, 1875. Defendant's laying was faulty—there was a clay joint, with a thin layer of cement over it. A fine of £5 and 12s. costs was imposed.

Building Plots for Nothing.—The curious case of an owner of building plots having to fight an action to keep his own property was heard last Wednesday in the Queen's Bench Division of the High Court of Justice. The land was at Mill Hill, and for twenty-one years had apparently been ownerless. A neighbouring resident, however, had grazed his donkey upon the plots, had mowed the grass upon them, and had finally parted with his "vested" rights to another neighbour, who in his turn sold them to a Mr. Alder. Then suddenly appears the original owner, Mr. Dudman, a grocer, of Hampstead, who informed the judge last week that he was not aware that he had ever parted with his rights in the land. The Court agreed that Mr. Dudman's claim had never been abandoned.

Knaresborough Building By-laws: Builder Fined.—On Wednesday last, at the Knaresborough Petty Sessions, the Bench gave their decisions in three cases in which John Brooks, builder, Harrogate, was charged with contravention of the building by-laws of the Knaresborough Rural District Council. These cases were heard at the last court, and the decision adjourned until the property had been viewed. For letting a house without having first obtained a certificate Brooks was fined £1 and costs. For not having sufficient air-space to certain property, formerly used as a lock-up shop, but now connected with a house, Brooks was also fined £1 and costs. The chairman said the defendant appeared to have acted in a sprit of defiance towards the Knaresborough Rural District Council throughout. With regard to the third case, in which defendant was charged with bringing forward part of a house beyond the adjoining building line, the Bench had come to the conclusion that a conviction could not be sustained, and the summons was dismissed.

Is Hoisting an Iron Girder "Engineering Work"?—On November 13th the case of *Cosgrove* v. *Partington* was heard in the Court of Appeal. It was an appeal from an award of the Judge of the County Court of Lancashire, holden at Oldham, in an arbitration under the Workmen's Compensation Act, 1897. The injured workman was at the time of the accident engaged with other workmen in putting a fifth storey on to a mill. The work included the hoisting of iron girders by means of a steam winch. The County Court Judge found that the workman was employed on an "engineering work" within the meaning of the Workmen's Compensation Act, and made an award in his favour. The employer appealed on the ground that the employment was not on an engineering work. The Court, without calling upon counsel for the workman, dismissed the appeal. The Master of the Rolls said that the point was whether the employment of the workman at the time of the accident was employment on "engineering work." Section 7 of the Workmen's Compensation Act said, by subsection 1, that the Act was to apply to employment on or in or about a railway, factory, mine, quarry, or engineering work. Then subsection 2 defined "engineering work" as meaning "any work of construction or alteration or repair of a railroad, harbour, dock, canal, or sewer," and including "any other work for the construction, alteration or repair of which machinery driven by steam, water, or other mechanical power is used." The workman here was engaged in putting on a new top storey to a mill, which was either construction or alteration, and the work involved the use of a steam winch. Why was not this within the Act? It was argued by Mr. Ruegg that the words "any other work" ought to be limited to work *ejusdem generis* with what would ordinarily be called engineering work. But in his Lordship's opinion those words were used for the purpose of enlarging the meaning of engineering work. He did not feel inclined to cut down the meaning of the section, and he thought that the appeal ought to be dismissed. Lords Justices Collins and Stirling concurred.

Workmen's Compensation: Another Scaffolding Case.—In the Court of Appeal on Wednesday last the case of *Ferguson* v. *Green* was heard. It was an appeal from a decision of the Judge of the County Court of Lancashire, holden at Oldham, in an arbitration under the Workmen's Compensation Act, 1897. The applicant for compensation was a working plasterer. The employers were master plasterers who had entered into a contract with a building owner to do the plasterers' work to some cottages. The cottages had been constructed by means of a substantial scaffolding on the outside, they had been completely roofed, and the scaffolding had been removed. At the time of the accident the applicant was engaged on the work of plastering the internal walls and ceilings of one of the cottages, and in order to reach the ceiling and the higher parts of the walls of the room in which he was working he had constructed a platform by means of two trestles across which he had placed some loose boards. He had set on the boards a table, on which he manipulated the plaster, and he stood on the boards to do his work. Finding that the table was unsteady he used a hammer for the purpose of mending it, and while he was doing so a nail flew into his eye and he suffered severe injury. The Court allowed the appeal. The Master of the Rolls said that in this case the arbitrator had found as a fact that the arrangement of trestles and boards on which the workman was standing when he met with the accident was not a scaffolding within the meaning of section 7, subsection 1, of the Workmen's Compensation Act, and he had on that ground given his decision in favour of the masters. The County Court Judge had reversed that, and had given his decision in favour of the workman. This Court had consistently refused to give any definition in law of the word "scaffolding" as used in this Act. They had said that that question was a question of fact, and all questions of fact that arose under this Act were to be decided by the arbitrator in each case, this Court only sitting to hear appeals on questions of law. They had said this in one of the earliest cases under the Act. Then came three cases—*Wood* v. *Walsh* (1899, 1 Q.B., 1,009); *Hoddinott* v. *Newton, Chambers, and Co.* (1899, 1 Q.B., 1,018); and *Maude* v. *Brook* (1900, 1 Q.B., 575) in each of which they refused to meddle with the finding of fact of the tribunal below as to whether that which was alleged to be a scaffolding was a scaffolding or not. In *Maude* v. *Brook* the facts were not distinguishable in substance from the facts of this case. An arrangement of trestles and boards was used for the purpose of plastering the walls and ceilings of a building, and the County Court judge found as a fact that that arrangement was a scaffolding. Lord Justice Rigby and he (the Master of the Rolls) held that there was evidence on which the County Court judge could find that it was a scaffolding, and they refused to interfere. Lord Justice Collins came to the conclusion that the trestles and boards afforded no evidence of a scaffolding within the meaning of the Act. In his opinion, the County Court judge could not properly overrule the arbitrator's finding on a question of fact if there was any evidence to support it. He therefore thought that the award of the arbitrator must stand, although the result was that there had been two different findings on exactly similar facts. Lord Justice Collins said he was of the same opinion. It was now clearly decided to be the law that an arrangement such as that used in this case might be a scaffolding. Any arbitrator who directed himself now on the hypothesis that it could not be a scaffolding would be misdirecting himself. The arbitrator in this case had come to the conclusion, as a matter of fact, that the arrangement was not a scaffolding. It was difficult to see how he could, on the decided cases, so find. But he was at large to consider whether it was a scaffolding or not. In his opinion the County Court judge had pressed the decision of this court in *Maude* v. *Brooke* too far. Lord Justice Stirling delivered judgment to the same effect.

Roads and Footways: An Interesting Irish Case.—At Dublin, in Queen's Bench No. 2, before Mr. Justice Boyd and Mr. Justice Kenny, the case of *Kingstown Urban District Council* v. *Beckett* was recently heard. This was an application on behalf of the plaintiffs for an order setting aside an award made by Mr. William Collen in respect of certain works at Kingstown, on the ground of excess of jurisdiction, and that it was based upon mistake, or that the award should be referred to the arbitrator for reconsideration. The Right Hon. T. MacDermot, Q.C., appeared in support of the motion, and said he moved on an affidavit of Mr. Joseph Berry, engineer and surveyor to the plaintiffs, in which it was stated that William Beckett, builder and contractor, Dublin, entered into a contract for the formation of roads and footways at Eden Park Road, Kingstown, for the sum of £2,954 3s. 10d. Under a clause in the contract the Board reserved power "to execute any part of the works themselves, or to omit any or to add others, or to make additions to or deductions from, or alterations in them," and the clause went on to state that an addition to or deduction from the contract sum should be made according to the rates set forth in the schedule of prices. Before Mr. Beckett commenced any of the works he (Mr. Berry) had, by direction of the Board, prepared a new plan, which was submitted to Mr. Beckett, showing the work which was to be done, and by this plan a portion of the work was excluded, representing the sum of £337 6s. 10d. That was practically the sum in dispute. The affidavit went on to state that the final certificate was made out for a total sum of £2,616 17s. Mr. Beckett, being dissatisfied with the measurements, called in Mr. Patterson on his own behalf, and this gentleman said that £42 18s. 10d. should have been allowed in addition to the £2,616 17s. The deponent could not agree to this, but consented to increase the final certificate by £21 15s. 6d. The dispute eventually went to arbitration, and the award made was that the pathways were not constructed in accordance with the contract and specification. The arbitrator said: "A sum of £200 would, in my opinion, be required to put these roads into the condition in which they should have been handed over by the contractor. The causes of the present condition of the roads are the bad workmanship shown in their construction, and the deficient quantity and the inferior quality of the materials used." He then went into particulars as to defects in the work, and held that the contractor was liable for them. He then determined that the Council were to put the roads into proper condition, to maintain them to September 1st, 1900, and upon that date to pay to the contractor the sum of £2,954 3s. 10d., less the amounts already paid him, the costs of the arbitration, and the amount of £250 certified by the engineer to have been expended in putting the roads into proper condition and maintaining them to that date. Counsel said that the mistake the arbitrator fell into was that in place of making the deductions from the sum of the final certificate he made it from the original contract sum of £2,954. Mr. R. R. Cherry, Q.C., opposed the application, and said that the whole controversy was whether Mr. Beckett was to be paid by measurement or by the contract sum. Counsel submitted that he was to be paid in the last-named manner. Mr. Justice Kenny: "Did not the new plans involve the abandonment of work to the extent of £337?" Mr. Cherry: "They were somewhat less in amount, and were more favourable to Mr. Beckett than the original plans." Mr. Justice Boyd: "Was there any such statement as this:—'I have made certain deductions under clause 8 of the contract; having made these deductions, these are the plans showing the deductions and the amount of the con-

tract?'" Mr. Cherry said that, on the contrary, Mr. Berry admitted that he never made any omissions at all. That was the case Mr. Beckett made all through, and the arbitrator found in his favour. The contention of the Township Commissioners was not that omitted works should be measured at all, but that the man should be paid by measurement of the whole works. Mr. Beckett's case was that he claimed the bulk sum under the contract. If they refused to pay him that bulk sum, and said he was to be paid on the amended plans according to the measurement, then he said he was entitled to 15 per cent. on omitted works. They drew the sword and went to arbitration, and the arbitrator had found in favour of Mr. Beckett. Now the Commissioners wanted to set aside the award in so far as it was against them, and to preserve it where it was in their favour. Counsel submitted that in no view of the case could the plaintiffs succeed. The Court refused the application, with costs.

LEEDS AND YORKSHIRE ARCHITECTURAL SOCIETY.

AT the annual gathering of the Leeds and Yorkshire Architectural Society, held on November 12th at the Queen's Hotel, Leeds, Mr. W. Carby Hall, F.R.I.B.A., the President, remarked that, unlike the immediate past, the building trade had not tasted the apple of discord of late. He noticed, however, that there was a probability of a lock-out of bricklayers in the North, and the masons of Leeds and district were asking for a halfpenny per hour advance, so that they might earn the same wage as the bricklayers. The Society of Architects had, he proceeded, given their support to the principle, if not to the wording, of a Bill having for its object the compulsory registration of architects. The outlines of the Bill recently before Parliament were, in his opinion, very reasonable, and appeared to be framed in such a way that the profession as a whole would greatly benefit. At the same time, he felt there were objections to registration. One of these would be the compulsory registration of those men who had done, and were doing, so much mischief to the architectural profession, notably the speculative builders, clerks of works, furniture dealers, and a host of other tradesmen, who considered architecture to be on a par with insurance canvassing, and who entered the field and dubbed themselves architects, so that they might add another branch to their already (in many instances) multifarious callings. But would not this evil, he asked, go on increasing unless put a stop to, and would it not be much better to recognise this and stop it at the earliest moment? England was practically the only European country in which architecture was not a registered profession requiring a diploma before any man could commence practice, and if registration was made compulsory here the public generally would, he thought, obtain an advantage from the improved constructive and sanitary portions of the architect's work, especially in buildings designed for the artisan class.

Continuing, the President expressed pleasure that the Royal Institute had actively taken up the question of the reform of the law relating to ancient lights, and said all would admit the injustice and injurious operation of Lord Tenterden's Prescription Act of 1832. He hoped that some comprehensive system of legislation would be passed by which an architect, when he had a building to erect on a site where ancient lights surrounded him, might know at once what he could do, instead of being put to all the annoyance and cost of a visit to London to repel the issue of an injunction, besides suffering delay in the erection of the buildings and also many other evils.

The President announced that there had been practically no competition for the prizes offered by the Society. There was no competition for the silver medal offered for measured drawings of old work, nor for the design or construction prizes. Mr H. E Henderson was presented with four guineas for an essay on "Ancient Ecclesiastical Architecture in the Neighbourhood of Leeds," half of this amount being given by the President in recognition of the creditable character of his work. Mr. S. R. Day carried off the sketching prize. Subsequently a smoking concert was held.

Keystones.

A Mortuary for Ramsey is proposed to be erected by the Ramsey Commissioners.

Dulwich House, Penhill, Canton, Cardiff, has been transformed into a convalescent home for women and children.

Mr. W. L. Griffiths, architect and surveyor, of 29 High Street, Newport, Mon., has opened a London office at Oswaldestre House, Norfolk Street, Strand.

The Additions to the Fever Hospital, Sunderland, are being warmed and ventilated by means of Shorland's patent Manchester stoves, with descending smoke flues and patent Manchester grates, supplied by Messrs. E. H. Shorland and Brother, of Manchester.

Cheshire Lunatic Asylum.—The Cheshire County Council propose to greatly enlarge the County Asylum at Parkside, Macclesfield. It is proposed to build an infirmary annexe for 206 additional patients, also a department for 50 epileptic patients and a nurses' home. The plans have been approved by the Lunacy Commissioners. The estimated cost of the buildings and equipment is £75,000.

T-Square Club.—This Club has been formed for architects, artists, engineers and surveyors, and for students in these professions. The object is to promote friendly intercourse between the members by giving a series of smoking concerts, which will be held in the foyer of Covent Garden Theatre. The opening concert will be held this day (November 21st), when the chair will be taken by Mr. William Emerson, president of the Royal Institute of British Architects. More than 135 members have already joined the Club. Full particulars may be obtained from the hon. secretary, Mr. T. Wilson Aldwinckle, "Saratoga," Dacres Road, Forest Hill, S.E.

The Chelsea Pensioners' Memorial.—A monument is shortly to be placed in Brompton Cemetery to the memory of the 2 000 Chelsea pensioners who are buried there. The base of the monument will cover a space of about 10 or 12 square feet; its height is 25ft. The work is being carried out by Messrs. John Whitehead and Sons, of Rochester Row, Westminster, and Paris, Aberdeen, and Carrara. Messrs. Whitehead also supplied the design. The lower portion of the monument is composed of grey Aberdeen granite, and the upper part of red Peterhead granite. The ornamentations on the sides of the monument are to be made of gun metal, which is being supplied by the War Office. At the top of the monument is a trophy of seven flags. The cost of the monument, which will amount to between £300 and £400, is being defrayed by the Office of Works and the War Office.

Building Trades' Gift to the Nation.—The Chairman of the Building Trades' Gift to the Nation announces the receipt of a number of valuable contributions in money, collected primarily in the provinces. Among these contributions are:—£500 from the Birmingham Master Builders' Association; £200 from the building trades of Walsall; £65 from the Manchester Master Builders' Association; £20 from Mr. Warburton, of Manchester; £47 from the Nottingham Master Builders' Association; £9 from the Longridge Master Builders' Association, as well as many smaller contributions. Of recent London contributions, Messrs. Holloway Brothers have given fifty guineas, whilst their workmen have collected twenty-five guineas, and Messrs. Perry & Co's workmen have sent thirty-three guineas. All the above contributions, it will be observed, are again the result of a close co-operation between the masters, manufacturers and men of the trades concerned.

A New Board School in Paddington has been opened in Essendine Road.

The Waenfawr Board Schools, Risca, Newport, Mon., are to be altered and enlarged at a cost of £2,140. Mr. J. Pritchard is the contractor.

Two New Chapels at Clay Cross are to be built by the Latter-day Saints and the Primitive Methodist Gospel Mission, in Thanet Street and Revell Street respectively.

An Accident Hospital for Barry.—The Hospital Committee of the Barry District Council have accepted the design of Mr. W. E. Knapman, architect, of Barry, for an accident or surgical hospital for the town, to be erected on a site already secured at the Buttrills, about a mile from the docks.

Houses Coming Down in Fleet Street, E.C.—The houses from 23 to 28 are about to be demolished for rebuilding purposes. The site is of certain historical interest. Before the Great Fire the famous "Hercules Pillars" tavern stood on the spot, which was greatly frequented by Samuel Pepys, and is often mentioned in his "Diary."

An Arts and Crafts Exhibition of works by students of the Camberwell School of Arts and Crafts, Peckham Road, S.E., supplemented by specimens from the London County Council Central School of Arts and Crafts, is now open from 2 p.m. to 10 p.m., until the 26th inst., at the Technical Museum of the South London Art Gallery, Peckham Road, S.E. Admission is free.

Discoveries in the Sea.—Divers who have been at work in the sea between Cape Matapan and the Island of Cerigo, the ancient Kythera, Greece, report that they have seen statues and other archæological objects. They have brought to the surface a hand which must have belonged to a great bronze statue. The Government has undertaken the supervision of the further researches which will be made.

Proposed Addition to Rathdown Union Workhouse.—A Local Government Board enquiry was held recently at Loughlinstown, into an application from the Rathdown Board of Guardians for a loan of £4,500 for the erection of a Roman Catholic Church and Nuns' Residence within the Workhouse grounds. The application was opposed on behalf of a number of ratepayers in the Union.

The Fishery House, Maidenhead.—This well-known house, with its charming grounds and well-kept lawns sloping to the river, affords a view of scenery of remarkable beauty. About thirteen acres of the ornamental grounds are to be laid out as a building estate with about 800ft. of river frontage Restrictions will be imposed calculated to ensure a superior class of residence, and to maintain a lawn to the river for the owners of plots not directly on the river front. Several villas and bungalows are to be erected on the estate, and the architects, Messrs. Palgrave and Co., 28 Victoria Street, S.W., have instructions to complete them by next summer if possible.

New Buildings in Newcastle.—The Town Improvement Committee of Newcastle Corporation have passed plans for a block of model lodging-houses to be built upon land now occupied by Mountain's Wireworks, situated in Watson Terrace and Stepney Road. The building will accommodate 303 persons. The design show a neat elevation on both sides, three floors high. The position is an admirable one for such an institution. On the ground floor there will be the manager's offices, recreation rooms, reading rooms, stores, large kitchens, &c. On the first and second floors there will be 150 cubicles, which, though open at the top, are, from the high partitions, practically self-contained rooms. The open tops will give plenty of ventilation. Plans were also approved on behalf of the Caledonian Insurance Company for a four-storey building to be erected on a site adjoining the Friends' Meeting House in Pilgrim Street. The building will include warehouses reaching as far back as the Manors. Also plans for a block of warehouses to be built on the site of the Temperance Hotel, Charlotte Square, were passed.

COMPLETE LIST OF CONTRACTS OPEN.

DATE OF DELIVERY.	WORK TO BE EXECUTED.	FOR WHOM.	FROM WHOM FORMS OF TENDER MAY BE OBTAINED.
	BUILDING.		
Nov. 23	Great Yarmouth—Alterations	J. W. Argyle	Charles G. Baker, Architect, Town Hall Chambers, Great Yarmouth.

Surveying and Sanitary Notes.

Institute of Sanitary Engineers.—At a meeting of the Election Committee held on the 14th inst. the following were elected:—As Members: Messrs. T. R. Atkinson (Penrith), F. B. Howarth (Sedgeley, near Dudley), and H. E. Milton (Gravesend). As Associates: Messrs. H. J. Hammick (Stonehouse, Plymouth), H. P. James (Chesham), J. Jenkins (Harlow), and E. Vittorio (Surbiton).

Sanitary Inspectors' Examination Board.—The next examination for certificates of qualification for appointment of sanitary inspector or inspector of nuisances, under the Public Health (London) Act, 1891, will be held in London on January 15, and the four following days. Particulars will be forwarded on application to the hon. secretary, W. R. E. Coles, 1 Adelaide Buildings, London Bridge.

The Widening of Piccadilly.—Mr. W. Willett, a member of the Metropolitan Public Gardens Association, suggests that when the County Council widen Piccadilly the railings of the park should be set back 20ft., so as to provide a strip of green turf 20ft. wide outside the railings. The effect of a broad band of grass raised 12in. above the footpath, and protected by a stone kerb, would, he thinks, be very restful to every one passing through Piccadilly, and if the railings could be covered with ivy or hidden by means of a privet hedge the effect would be enhanced.

Drainage By-laws for London.—At the meeting of the Council of the Sanitary Assurance Association, held last week, Mr. Andrew Stirling in the chair, the new drainage by-laws, as drafted by the London County Council, were under consideration, and on the motion of Mr. W. S. Halsey, seconded by Dr. E. H. Willoughby, the following resolution was passed: "That, in the opinion of the Council of the Sanitary Assurance Association, the drainage by-laws proposed by the London County Council ought to be submitted to the New Metropolitan Borough Councils before they receive the force of law, and that the President of the Local Government Board be requested to submit the proposed by-laws to the said councils before deciding as to their confirmation."

New Companies.

Dublin United Coal Factors' Company, Ltd.

This company was registered in Ireland on October 20th with a capital of £1,000 in £1 shares, for the purpose of buying, selling, and dealing in coal, sand, lime, bricks, timber, &c. This company was registered on October 29th with a capital of £10,000 in £1 shares to acquire landed and other property, and to carry on the business of builders, contractors for public and other works, financiers, insurers, merchants, &c. The first directors (to number not less than three nor more than 12) are to be appointed by the subscribers. Registered office: 48 Cross Lane, Earlstown, Lancashire.

Parsons, Sherwin and Co., Limited.

This company was registered on November 3rd with a capital of £35,000 in £5 shares to acquire the business carried on at Nuneaton, Hinckley, Coventry, and elsewhere, as Charles Parsons, and to carry on the business of builders' furnishing and general ironmongers, builders, contractors, decorators, hardware dealers, metal trade valuers, auctioneers, &c. The first directors (to number not less than two nor more than seven) are J. F. Johnson and E. F. Melby (managing directors). Registered office: New Bridge Street, Nuneaton.

Ambrose Shardlow and Co., Limited.

This company was registered on November 2nd with a capital of £20,000 in £1 shares to acquire the business carried on by the trustees of the will of the late Ambrose Shardlow at Ealing Works, Washford, Attercliffe, Sheffield, and to carry on the business of ironfounders, hot water, electric, and general engineers, steel and iron masters, &c. The first directors (to number not less than three nor more than five) are Mrs. C. Shardlow, C. Moore, J. Lees, and A. T. Shardlow.

C. Whittaker & Co., Limited.

This company was registered on October 23rd with a capital of £120,000 in £10 shares to adopt and carry into effect an agreement for the acquisition of the business of ironfounders, &c., as carried on under the style or firm of C. Whittaker and Co., Limited (incorporated in 1897), at the Dowry Street Ironworks, Accrington, Lancashire, and also for the acquisition of a similar business carried on by Furneval and Co., Limited, at the Union Foundry, Haslingden, Lancashire, as mechanical, general, and electrical engineers, brass and iron founders, machine tool makers, smiths, ironmongers, furnishers; as millwrights, iron and steel converters, woodworkers, builders, contractors, painters, decorators, metallurgists, water-supply engineers, art metal workers, upholsterers general house furnishers. The first directors (of whom there shall be not less than three) are T. Whittaker, C. J. Whittaker, T. Whittaker, jun., and L. Whittaker. Registered office: Dowry Street Ironworks, Accrington, Lancashire.

London Wood Mantel and Art Joinery Company, Limited.

This company was registered on November 2nd with a capital of £5,000 in £1 shares to adopt an agreement with S. Callow and J. W. Wright, and to carry on the business of wood mantelpiece, and overmantel manufacturers, joiners, cabinet makers, upholsterers, decorators, &c. The first directors (to number not less than three nor more than five) are J. E. Brown, W. B. Clarke, N. J. Codner, C. Williams, and J. W. Wright. Registered office: Saracen's Head Buildings, Snow Hill, E.C.

Nevin Bay Granite Quarry, Limited

This company was registered on November 5th with a capital of £25,000 in £1 shares to adopt an agreement with F. Hall, and to carry on the business of quarry, mine, and colliery owners, stone, metal, clay, coal, and mineral merchants, smelters, engineers, &c. The first directors (to number not less than four nor more than nine) are H. Seddon (chairman), T. N. Leighton, T. S. Bowers, A. E. Hall, T. B. Edwards, and E. N. Dunderdale. Registered office: 7 St. James Square, Manchester.

The Birmingham Master Builders' Association held its annual meeting and dinner last week, Mr. F. G. Whittall (president) in the chair. The committee, in presenting their annual report, regretted to have to record a falling off in the volume of trade, owing, without doubt, to the high prices of material and labour now ruling. The first duty that devolved on the committee during the year was to deal with the notices from the plasterers and the masons for an advance of ½d. per hour, bringing the stonemasons' rate of wages to 10d. and 10¾d., and the plasterers' to 10d. per hour, who were given the asked for. Owing to the rapid advance in the prices of all material, it has been necessary to revise the schedule of day-work prices. The balance sheet showed a sum of £187. The president (Mr. Whittall), the vice-president (Mr. Albert S. Smith), the treasurer (Mr. G. Twigg), the auditors (Mr. T. Johnson and Mr. J. S. Surman), and the secretary (Mr. Ernest J. Bigwood), were re elected, and the committee, with one alteration, was re-elected.

WATFORD URBAN DISTRICT COUNCIL.
TO BUILDERS AND CONTRACTORS.

The Watford Urban District Council are prepared to receive TENDERS for the ERECTION of a TECHNICAL SCHOOL as Additions to the Watford Public Library, in Queen's Road, and for Alterations to the latter.

Drawings, specification, and conditions of contract may be seen at the Office of the Architect, Mr. W. H. SYME, F.R.I.B.A., 4 High Street, Watford, from whom bills of quantities and forms of Tender can be obtained on deposit of Two Guineas, which will be returned after receipt of a bonâ-fide Tender.

The Council do not bind themselves to accept the lowest or any Tender.

Sealed Tenders, on form to be supplied, endorsed "Tender for Technical School," must be delivered to me on or before TWELVE o'clock noon, on THURSDAY, NOVEMBER 29th, 1900.

H. MORTEN TURNER.
Clerk to the Watford Urban District Council.

Council Offices,
No. 14 High Street, Watford.

TO BUILDERS.

The Commissioners of H.M. Works and Public Buildings are prepared to receive TENDERS for the ERECTION of a NEW CUSTOM HOUSE at Southampton.

Drawings, specification, and a copy of the conditions and form of contract may be seen on application to the Collector of Customs, Custom House, Southampton.

Bills of quantities have been prepared for the use of builders by Messrs. WIDNELL and TROLLOPE, of 13 Parliament Street, London, S.W., and together with forms of Tender may be obtained at the undermentioned Office on payment of One Guinea. The sums so paid will be returned to those persons who send in Tenders in conformity with the conditions specified below.

The Commissioners do not hold themselves responsible for the accuracy of the quantities, nor do they bind themselves to accept the lowest or any Tender.

Tenders are to be delivered before TWELVE o'clock on TUESDAY, the 11th of December next, addressed "The Secretary, H.M. Office of Works, &c., Storey's Gate, London, S.W." and endorsed "Tender for Southampton Custom House."

H.M. Office of Works, &c.
November, 1900.

ROMFORD SCHOOL BOARD.
TO BUILDERS AND CONTRACTORS.

The above Board are prepared to receive TENDERS for the ERECTION of an INFANT SCHOOL to accommodate 290 children.

Plans, specification, and conditions may be seen at the Albert Road School, Romford, between the hours of TWELVE and FOUR p.m., except on SATURDAYS.

Bills of quantities can be obtained at my Office on payment of Two Guineas, which will be returned on receipt of a bonâ-fide Tender.

Tenders, under seal, endorsed "Tender for Infants' School" must be delivered at my Office not later than TWELVE noon on MONDAY, the 10th day of DECEMBER next.

The person whose Tender is accepted must enter into a bond, with two responsible parties as sureties, in the sum of Five Hundred Pounds for the due performance of the contract.

The Board do not bind themselves to accept the lowest or any Tender.

By order,
WILLIAM SMITH,
Clerk.

No. 24 North Street, Romford.
November 1900.

WALTHAMSTOW SCHOOL BOARD.
TO BUILDERS AND CONTRACTORS.

The Walthamstow School Board invite TENDERS for the ERECTION of NEW SCHOOL BUILDINGS in Gainsford Road, Walthamstow.

The drawings and specification may be seen, and bills of quantities obtained, on and after NOVEMBER 22nd, 1900, at the Office of the Architect, Mr. G. E. T. LAURENCE, A.R.I.B.A., 22 Buckingham Street, Adelphi, W.C., between the hours of TEN a.m. and FIVE p.m.

Applications for copies of quantities must be sent to the Architect before the above date.

A £5 note must be deposited for the quantities, and another £5 note must be enclosed with the Tender, both of which will be returned to those sending in bonâ-fide Tenders.

Tenders to be endorsed "Tender for New Schools," and to be addressed to the Clerk of the School Board, Clevelands, High Street, Walthamstow, and delivered not later than SEVEN p.m. TUESDAY, the 4th DECEMBER, 1900, on which day they will be opened at EIGHT p.m.

The Board do not bind themselves to accept the lowest or any Tender.

T. W. LIDDIARD,
Clerk to the Board.

School Board Offices,
High Street, Walthamstow,
November, 1900.

N.B.—The conditions to be complied with as to the hours of labour and the payment of wages can be seen with the specification

Morrison & Ingram's
SANITARY APPLIANCES.

THE "DENSITAS" CLOSET SUITE

Comprises an excellent wash-down, deep-seal Closet, made in Midway Caneware, double thickness, buff out, white glazed inside, deal seat, 2½ gallons, strong Caneware Cistern, with cast-iron cover and brackets, also wrought-iron flushing pipe, 2ft. long.

Price of Suite Complete,

48/7

Carriage Paid.

These closets are expressly designed to save cost in fixing, and are suitable for Workmen's Dwellings, Schools, Warehouses, and the like. They are confidently recommended; also made in finest Porcelain-ware—white, printed, or decorated—for cottage and villa use.

Prices and Particulars on Application.

Brass & Ironfounders AND Sanitary Potters.

MANUFACTURERS OF
All kinds of Sanitary Appliances.

Morrison, Ingram & Co.,
LIMITED,

An Architectural Causerie.

Official Peculiarities. THE names of the eight architects who submitted designs for the Holborn-Strand buildings having at length been announced, it is perhaps interesting to note that the predictions made at the end of our criticism (see page 251 of our issue for October 31st) are perfectly correct. We cannot understand why the Council has exercised such secrecy. In a case of this sort the only reason for not attaching the names of the architects to the respective designs is that the assessor's award may be unaffected by any personal taste or distaste for particular architects' work. It was therefore an unreasonable action of the Council's Committee when placing these designs on exhibition to continue to withhold the names, as the assessor's award had then been made and sealed. The same peculiarity was observed in the selection of the numbers, which were apparently chosen haphazard, though one can see no valid reason for doing so. It has been remarked by contemporaries that, though of course they knew from the first who were the authors of the several designs, they sealed their mouths in deference to official ruling and in fairness to Mr. Norman Shaw. Such obedience carries its own reward. The only thing which still remains to be published is Mr. Shaw's report. Remembering that he is the greatest living architect in this country at the present time, his criticism of the Holborn-Strand designs will be read with more than usual interest.

Underground Travelling. CONSIDERABLE attention was drawn last week to the fact that electricity is to take the place of steam on the "Underground," and that Bills will be placed before Parliament next session for the construction of many new underground lines. There are some things whose objectionable qualities become lessened by familiarity, but the Inner Circle cannot claim this salve—it is just as offensive on the first journey as it is after twelve months' travelling. We therefore welcome the proposed change, which will enable persons to go from one part to another without having to undergo a sulphurous treatment, with the addition, during summer time, of a vapour bath. What must be the condition of the roofs of the tunnels can only be imagined, but judging from the state of the numerous ventilators or "breathers," which disfigure everything around them, it must indeed be bad. Under the new scheme the tunnels will be lined with tiles in parts, and considering that the conversion from the new to the old system is estimated to cost £500,000 only, one is surprised that this most desirable change has not been effected long ago, for it must be admitted that the "Underground" is a disgrace to London. The experimental electric train which was running till quite recently between High Street, Kensington, and Earl's Court doubtless proved a success, and it is stated that a somewhat new system has been developed from it. This will include the adoption of Professor Sprague's invention for abolishing the locomotive by fixing motors under alternate carriages, or on every carriage. This is said to give a higher speed and a more equal distribution of weight. Of the many other undergrounds proposed to be constructed, it may be remarked that there is no semblance of unity among them, each proposal being restricted to its own particular line of route: the result is that several lines practically coincide, and, at least under the City, would result in a perfect network of tunnels. What is wanted is an intercommunication of lines like that existing in some American cities.

Wanted—A Housing Manager. THE London County Council is to be congratulated on having adopted the recommendation of its General Purposes Committee to form a Housing Department with a "Housing Manager" at the head of it. To find fault without suggesting a remedy is a very simple matter, and the Council has received much of this kind of attention, but when the figures relating to the cost of land and building are produced many reformers feel uneasy. It should be remembered that before the Council can take credit for a profit it must provide for repairs and renewals, for interest on capital and outlay, and make provision for a sinking-fund sufficient to replace in sixty years the whole of the money spent originally on the land and buildings. The first block of buildings was opened in 1894, and up to March 31st last 10,060 persons had been re-housed at a cost of £609,438; progress had also been made with proposals for the accommodation of 31,141 more, involving a further expenditure of £1,235,789. It will be seen that when tens of thousands of people have to be dealt with the housing problem becomes most complex. Opinions differ as to the proper method of effecting improvement: while railway facilities are what they are we cannot see that the Council could materially alter its programme with advantage, though it must be admitted that many of the displaced tenants do not return to the new houses: on the Boundary Street estate, for example, the class accustomed to the one and two-roomed tenements did not figure prominently among the applications for new accommodation. At present seventy persons, from surveyors to caretakers, are employed upon the 1,976 tenements owned by the Council. In the near future, when these tenements have increased to about 7,700, and the rents received amount to £160,000, about 248 officials will be needed. It is hardly necessary to remark that the official in whose hands the whole government of the Council's housing schemes will rest needs to be a very exceptional man, and we hope that the Council will be happy in their selection. Such a man ought to be obtainable for £800 a year. While dealing with the London housing question it is opportune to refer to the scheme which will be considered by the Council on December 3rd. By this it is proposed to purchase an estate of 31 acres at Norbury, in Surrey, and to erect there 551 single cottages of three, four, and five rooms, and 211 double cottages containing tenements of two and three rooms. Two roads, 45ft. wide and planted with trees, would be formed from east to west through the estate, in addition to subsidiary streets 40ft. wide. The estimated cost of the land (which is about a quarter of a mile from the county boundary), including brickmaking plant and incidental expenses, is £20,000. But even here, outside London, the rents proposed are as much as 7s. and 9s. for single cottages of three rooms, 6s. 6d. for double cottages of three rooms; two rooms and small kitchen, 6s.; four rooms, 9s. 6d.; and five rooms 11s. to 11s. 6d.; in addition to which the workman would have to pay a railway fare of 4d. per day in going to and coming from his work.

NO. 94 PARK STREET, LONDON, N.W. A. H. BELCHER, ARCHITECT.

94 Park Street, N.W. THIS was an alteration to the ground floor and basement only. The old premises belong to Messrs. F. Higgs and Son, and occupy a corner site with the end octagonal on plan on the ground floor and circular on plan above. The business was that of provision and dairy produce and of a cheesemonger, and therefore there was fortunately no stipulation that the shop front should be "all glass," as would have been the case if the business had been that of a draper for the exhibition of goods. The only stipulation was that the lower portion of the sash should lift up, and that this should be used below the shop front. Advantage was taken of this for the introduction of squares in the upper part and of the scheme shown in the perspective on this page. The architect, Mr. A. H. Belcher, says: "The lettering on the bellied frieze is not shown in the drawing, as this would, I understand, prohibit it from exhibition at the Academy"—where the water-colour drawing from which our illustration is made was shown this year.

WOOTTON WAWEN CHURCH, WARWICKSHIRE.

BY CHARLES M. C. ARMSTRONG.

OF the many hundreds of cyclists and others who daily travel on the fine old turnpike road that runs from Birmingham to Stratford-on-Avon, few give more than a turn of the head to the very interesting old church of Wootton Wawen, so beautifully situated on rising ground in the centre of the village. For those who can spare time to more thoroughly explore it, these notes and sketches have been prepared, in the hope that they may lead others to take interest in the building.

At fourteen miles from Birmingham we reach the little market town of Henley-in-Arden, where there are many curious half-timbered houses, the remains of an old market cross and a rather debased Perpendicular church; although retaining many characteristics of bygone days, the place has of late been overdone with tea-houses and tin tabernacles for beanfeasters. A quarter of a mile to the north,

WOOTTON WAWEN CHURCH, FROM THE NORTH-EAST.

separated by the Alne, is the very interesting Norman church of Beaudesert, locally pronounced "Belser." Though the south entrance arch has been much restored, it has some fine examples of zigzag and lozenge recessed Norman mouldings; but the chancel arch is in a more perfect condition—that is, it is rather less restored. A picturesque lych-gate has recently been placed at the entrance to the churchyard. For the greater part of it the architect has been able to make use of old materials, so that it looks quite in keeping with its surroundings. The poet Jago was born at Beaudesert in 1715, and was buried there in 1781, having died at Snitterfield, in the same county.

Two miles further on we reach Wootton Wawen. As for its peculiar name, there is no question that it originally arose from its situation among woods, having the addition of Wawen from one Wagen (commonly called Wawen) who was lord of this place before the Norman Conquest. Dugdale says: "This Wawen was a man of great antiquity in his time. In consideration of his stout fighting for Duke William against King Harold, he was rewarded with such vast possessions in several English counties, amongst which this town of Wootton, with the rest of Wagen's lands were part." He eventually took the name "Stafford" from his seat in that county, and from him descended the noble family of that name. When Edward Stafford, Duke of Buckingham, attained it, Henry VIII. granted it to the Marquis of Dorset, and on his attainder Queen Mary gave it to Sir John Grey, from whom it was purchased by the Smythes, who still hold it. The extent of this Wootton was then certified to be seven hides, there being at the time a church and two mills. Many centuries later Dugdale says: "In the Township of Wootton there are fifty-five families and twelve teams kept."

The church, dedicated first to St. Mary and subsequently to St. Peter, was given to the monks of St. Peter of Conches in Normandy by this Robert of Stafford shortly after the conquest of England by Duke William, and appropriated for them by Roger, Bishop of Worcester, on November 3rd, 1178.

There is no doubt that a monastery of Benedictine monks stood here in the fourteenth century, probably in connection with the priory of Maxstoke in the same county, for we find that "shortly after King Henry IV. (by the deposal of King Richard II.) attained the crown, taking into consideration that these *Priores alien* were originally founded to the honour of God, and that through the frequent seizures of them into the hands of his progenitors, by reason of the wars with France, the monks were driven away, and the houses so wasted, that such divine service as had antiently been established therein, was wholly withdrawn." Its revenues were granted in the first place by Richard II. to St. Anne's Priory near Coventry—one of the few remaining Carthusian houses in England, built in 1381—and in later years by Henry VI. to King's College, Cambridge, in whose gift the living still is.

The present church, of which the greater part is of the fourteenth century, is built of rubble and stonework, and is a very striking object, standing well against the sky-line, with the dark firs and fine elms of Wootton Hall at its east end. It is said to claim a higher antiquity than any other of the many interesting Warwickshire churches, and the late Bishop of Worcester, Dr. Phillpotts, declared it to be the most interesting church in his diocese, mainly on account of the very evident and considerable remains of pre-conquest construction; at least three-fifths of the tower are of Saxon workmanship, though from the exterior this is difficult to discern, as the north side of the tower (the only one exposed) is unfortunately stuccoed over; internally the "strip" and "long-and-short" work is very conspicuous, the once central tower standing on four fine specimens of Saxon arches. On the north side of the nave, there is a blocked-up semi-circular-headed doorway, and another below the west window, whilst traces of Saxon rubble-work may be discovered in various portions of the north wall.

On reference to the accompanying illustrations it will be seen that the church consists of north and south porches (the north doorway being now closed), clestoried nave, south aisle, a central embattled and pinnacled tower, chancel, and a chantry chapel of exceptionally large dimensions, quite out of proportion to the remainder of the building.

Entering by the south porch, which is built between, or rather on, two of the three buttresses which help to support the Early Decorated south aisle, the fourteenth-century font claims attention, standing on modern sandstone steps; the basin is octagonal on plan and is supported by sculptured hooded monks' heads. The south aisle is separated from the unusually wide nave by three pointed arches and has been re-roofed, the church having been restored in 1881, though there is little evidence of this externally. The chancel is unfortunately in a very bad condition at the present time, damp green mould and cracked plastering surrounding the north wall's beautiful Decorated windows.

The west end has a fine Perpendicular window of five lights, with sculptured corbel heads, internally, of King Edward III. and Queen Philippa. The pulpit, octagonal in shape, is a good example of fifteenth-century oak carving, and stands between the second and third bays of the nave. The east end of the nave has a carved oak screen, which has been much altered. On either side of it, and joining with it, are two large enclosed pews with open oak pannelling, not unlike the people's altar at Burford in Oxon, but without a tester over. There has been much altercation as to what these were originally intended for, but there seems to be little doubt that they were used for chantry chapels, as three brackets for figures are still to be seen at the east end of each. The altar is now placed in the east end of the tower, the chancel not being used: access to this is obtained by what must surely be one of the smallest chancel arches in the country, measuring only 4 ft. 9 in. across. The northernmost of these four "long and short" circular-headed arches has been filled in with a modern plain glazed window, which rather spoils the effect, though the light is necessary. The chancel, divided from the chantry chapel by two double-faced arches and a plain seventeenth-century screen, has a very fine Decorated window of seven principal cinquefoiled lights, the mullions of which are carried straight up to the head, these being also divided into twenty-two smaller panel lights. Around the edge of the interior of its jambs and architrave is the curious and almost unique feature of a continuous series of crockets set in a hollow moulding, a double row above the springing of the arch and a single row below; this occurs also on the exterior, but the crockets are placed further apart. The finial-headed pews, west screen and altar rails in the chancel are of seventeenth-century date.

The church has some interesting tombs, the oldest of which stands against the north wall of the chancel; this is a high stone-stuccoed tomb, with plain shields at the sides, bearing a sculptured effigy in alabaster of an armour-clad man, his feet resting upon a long-eared dog with a chain collar round the neck. This represents John Harewell, who died in 1428, bequeathing his body to be buried in the church. The figure is unfortunately badly mutilated, initials and dates of the vandal English sight-seer being much in evidence. The Harewells were "ranked amongst the superior gentry of this shire"; a female descendant of this same Harewell married a Smyth, and "from him was lineally descended Sir Charles Smyth, Knight, who manifested his fidelity to the late King Charles the First, in the times of his greatest distresses, by divers considerable aids; in consideration whereof, he was, by Letters Patent, in the nineteenth year of his reign, advanced to the degree of a baron of this realm, by the title of Lord Carrington of Wootton, and subsequently to Viscount Carrington of Barrefore, within the Province of Connaught, in Ireland. This Viscount Carrington having occasion to travel in France, lodging at Pontoise, was there barbarously murdered by one of his own servants in February, 1664, for lucre of such money and jewels as he then had at that place."

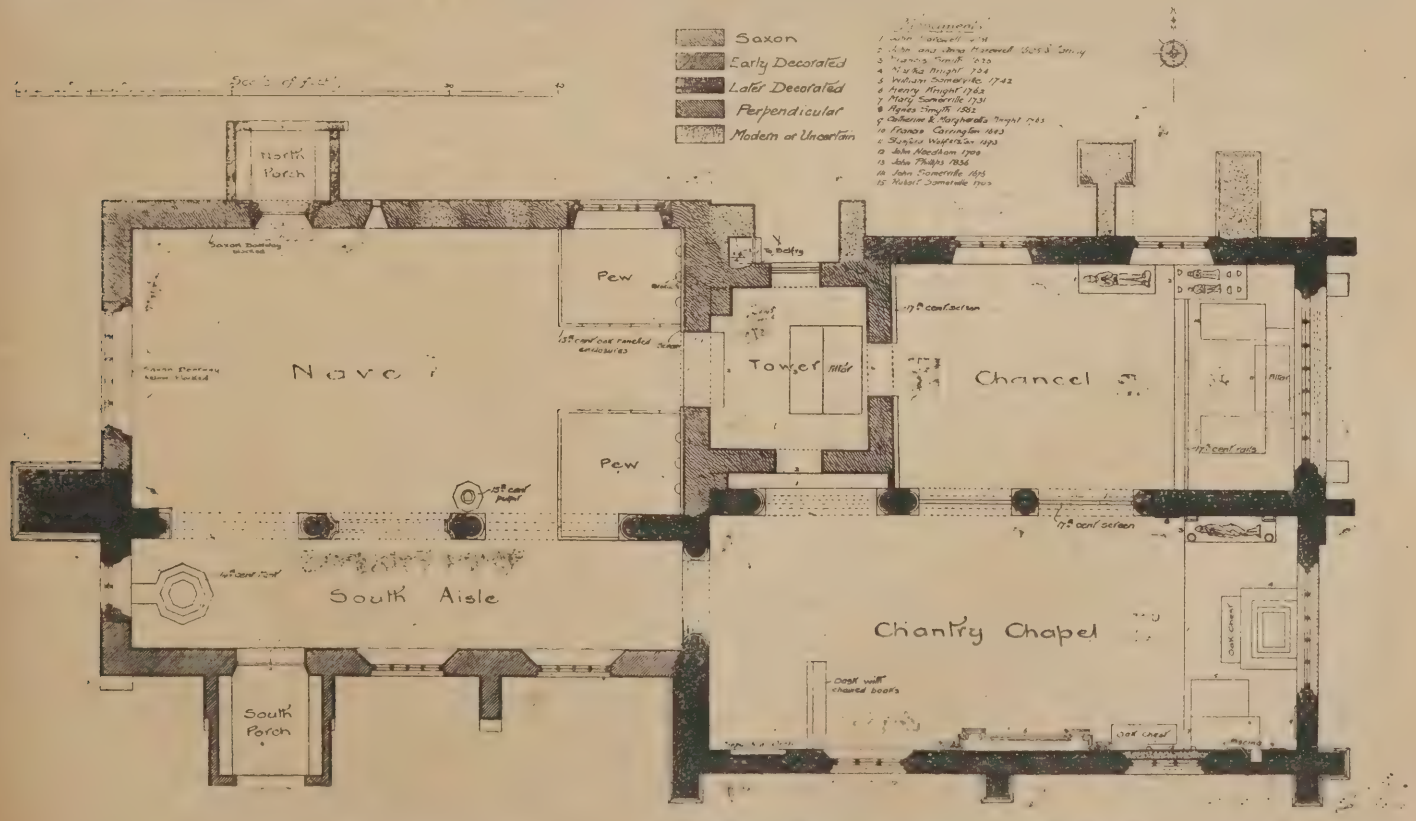
Within the altar rails is another tomb to the Harewell family covered with a dark-coloured marble slab, with finely-preserved inlaid brass

effigies of John Harewell (who died in 1505) and his wife Anna; the dress of the period is well represented. Underneath these figures are brasses to their ten children, whilst the whole is completed by four coats of arms, amongst which may be discovered the heads of hares as armorial bearings. The following inscription in brass runs round the edge :—"Hi jacet Johes Harewell,'armig' et dna Anna qondam uxor eius ac nup' uxor Edwardi Grey militis qui quidem Johes obiit X° die Aprilio anno dui MV°V et qui quidem Anna obiit. . . . . die . . . a dui MV . . . . quorum aiabz ppitietur deus." No doubt this monument was erected before the wife's death, causing the omission of that date. Under the altar lies Stanford Wolferstan, apparently a local doctor, who died in 1698, as the hardly decipherable doggerel under his name implies,

"To souls and bodies too he med'cines gave
Like his great Master, willing both to save."

The chantry chapel has a series of monuments and tablets upon its walls and floor, the more interesting of which I have endeavoured to locate on the plan. Against the north wall is a high canopied tomb, supported by pilasters and Ionic columns, of a man in armour reclining on his side; this represents another of the Smith or Smyth family who died in 1626. A very ugly monument and urn stands against the east window, whilst a pretentious erection of Corinthian columns and wings occupies the centre of the south wall. Perhaps the memorial of most interest in this chapel is that to William Somerville (who died in 1742), the well-known author of "The Chase" and other poems. His epitaph is said to be his own composition; the present vicar, who happily takes a deep interest in the church, has recently caused a memorial brass to his memory to be fixed on the north side of the nave. A richly-decorated but apparently unfinished piscina stands in the south wall.

In the chancel there are two old oak chests. The one at the east end is at least three hundred years old; standing on four pannelled legs, it has three wrought-iron locks, and double fleur-de-lis ironwork; of this my cicerone said, on the occasion of my first visit to the church "'twas worth a king's ransom!"



A long desk, forming part of the primitively enclosed vestry at the west of the chapel, contains eight chained theological works, published between 1578 and 1673, the oldest two being "Christian Religion," by John Calvin (1578), and "Common Prayer" (1633); some of these books are in the most perfect state of preservation, and but for their quaint print and discoloured paper might have been issued this year. The registers date from 1654.

The belfry, which is reached from the outside —further proof of the building's ancient character—contains six bells, with dates ranging from 1719 to 1742 engraved upon them; one bell has also the letters of the alphabet from A to S inclusive. The fine deep oak beams in the tower are worth inspecting, also the open framing which supports the roofs of chancel and chantry.

The north porch is plain, but the doorway contains a beautiful example of Late Decorated mouldings, upon the jambs of which hangs a delightful old door with Saxon double-headed nails; the door handle itself is a real gem in ironwork, wrought in the days when the local blacksmith was a craftsman and not a machine, as he appears to be at the commencement of the twentieth century. The scutcheon is pierced with a trefoil-headed design of very fine workmanship, and the ring to the heavy circular handle has two hammered pieces of iron soldered on; the accompanying drawing of which will give some idea of its merits.

There are many other interesting bits which are well worth studying and sketching, such as the four beautiful Perpendicular windows on each side of the clerestory, an old sun-dial on the south wall, the time-eaten gargoyles and crocketted pinnacles, round which the rooks circle with a never-ceasing call. In the village, also, days might well be spent amongst the half-timbered houses: the old Georgian farmhouse with its delicately-designed pedimental head over the front door; that truly rustic village inn "The Traveller's Rest"; or again, at the Stratford end of the village, what a charming view is obtained from the old bridge which spans the little river Alne. Fringed by beautiful trees, the Italian mansion of Wootton Hall, built in the seventeenth century, with the Smythe coat of arms on its huge pediment, is very conspicuous, whilst built into the bridge itself is an old milestone dated 1806, informing us that we are exactly 100 miles from London's turmoil. Lower down the road is one of the remaining mills mentioned by Dugdale; it cannot be called beautiful, with its huge front elevation and many formal windows; yet for those very reasons it appeals in a certain way to an observer on first entering this village on a summer's day.

But the church is Wootton Wawen's magnet, or ought to be, and yet how few know more than its odd name. The admission charge of sixpence cannot surely keep away visitors, for in no better way could those who have a love for our old buildings lay out this modest sum.

WOOTTON WAWEN CHURCH, GROUND PLAN. MEASURED AND DRAWN BY C. M. C. ARMSTRONG.

SOCIETY OF ARCHITECTS.

PRESIDENT'S ADDRESS.

MR. T. WALTER L. EMDEN delivered his presidential address to the members of the Society of Architects on Thursday evening last. He said: My thanks are again due to the Society for electing me unanimously for the fourth year to the presidential chair. I need only say I shall give my best attention to the work of the Society.

Whatever may be the position of this Society, and being the youngest of the English societies it must be looked upon as the junior society, it undoubtedly has succeeded in making a position for itself which is at all events unique as far as the architectural societies of England go. It is the first Society which has ever taken up as its principal object the improvement of the status of the architectural profession upon a solid and sensible basis. Whatever may be said of the work of the Institute or of any of the other architectural societies, and they have done much good work, they have not lent their aid to the principle of the registration of the profession and the system of compulsory education and examination before registration.

It seems extraordinary that the oldest profession in the world should in this country, which is supposed to stand foremost in civilisation, never have been guarded by any scheme of education or examination, and that no attempt has been made by the older societies to place their members on a level with the foreign branches of the profession.

Registration.

It seems hardly resonable to suppose that there can be any real benefit obtained from the institution of the various architectural societies when voluntary education and voluntary registration is the limit to which they attempt to elevate the profession.

If the profession is to be recognised in the manner which its antiquity and standing demand, and its power for good or evil for the public interests warrants, then certainly it ought not to be a profession so open, so uneducated,

and so easy of entry as the profession in England is at the present time. The education of its members cannot in any way deteriorate from their artistic ability, while a thorough knowledge of the profession, and all its necessities in construction and sanitation, cannot but add to the protection of the public and to the ennobling of the art of architecture, which we profess to practice.

The Society of Architects has attempted—and if it has not been able to do more it is for lack of support from the Institute and other societies—to press forward the work of compulsory education and registration; which should long ago have been made the chief aim of every architectural society in existence. That we may succeed in awakening the Institute to its obvious duty is the hope of every member of the Society, and if we do not succeed in this we must continue the work ourselves. That we have not succeeded sooner is to be accounted for solely by the opposition, active and passive, which is shown by the Institute, and by other societies influenced more or less by it. The eventual outcome will no doubt be what common-sense points out as being absolutely necessary; that is, everyone who proposes or desires to enter the profession will be first compelled by Act of Parliament to show himself competent to do so.

The protection of the title of Architect is one apparently of international importance, as we find at the late International Congress at Paris that a resolution was adopted in favour of restricting the practice of architecture to those provided with a proper Government certificate, placed within the reach of all by the diffusion of architectural education, and so protecting the public by preventing incompetent persons from entering the profession. I would earnestly appeal to those who desire to see the status of the profession raised, and the door closed to incompetent men, to join this Society, and to lend their aid to the work of registration which we have taken in hand.

Architectural Training.

A good deal of controversy is at present proceeding as to what should be the proper training for an architect. Many think that the present system of pupilage and premiums should be replaced by a course of training in studio or college, but while the present method may be open to improvement, it seems to me that there cannot be much wrong with the system which has produced such distinguished men as those who now adorn the profession. The discipline and business habits now obtained by pupils who are trained in an office could not be obtained by attending classes or lectures alone. It is by a combination of the two that improvement can be effected. Every pupil's articles should contain a provision for him to attend regularly and at stated times classes and lectures provided at some recognised centres.

But I do not see much chance of this improvement until we have a scheme arranged by, say, the London University, with lectures, classes and professors similar to those existing on the Continent and in America. To multiply the present so-called architectural training centres is only peddling and dabbling with the question and will only increase the evils now existing; it will not provide a sound and solid basis upon which to build a proper architectural college. If all the existing teaching agencies were to combine their forces, something satisfactory might be evolved.

Light and Air.

Passing from this question, all-important as it is, I come to another matter which it seems to me has been dealt with somewhat late in the day. Not until it had grown into an evil of such dimensions as to make building operations almost prohibitive in many cases have the Institute attempted to deal with it; even then, only after this Society had brought the matter into prominence by its petition to the Lord Chancellor and by ventilating the question at its meetings. The matter is one which can be so simply and fairly dealt with, as is the case in Scotland, that it is difficult to understand why it has not been more prominently brought before the public at an earlier date. However, the Society may be pleased that its efforts in this direction have met with the approval of the profession generally, and that the Institute have now come forward and formed a committee to deal with the question. We hope that it will press forward without delay until this much-needed reform is accomplished.

The members of the Society must not, however, think that they have now done their duty and need not further press the question upon public attention. Those who grow old sometimes grow feeble, and it is not, therefore, to be taken for granted that because the Institute has put its shoulder to the wheel that it will press forward vigorously for this important alteration in the law of England. We must, therefore, on all occasions still continue to ventilate the subject, and in doing so we trust to help the endeavours of the Institute and at the same time to make up for any lack of vigour which the elder Society may show in dealing with it.

Rebuilding London.

It has been suggested that the improvements and alterations made in London streets are not made upon any consistent plan, and that London should be laid out on a great comprehensive scheme irrespective of its present streets. Such a suggestion, of course, is absolutely impracticable in a busy business city of the magnitude of London to those who make a study of the problem. Apart from the fact that it is probable that no agreement would ever be arrived at as to the best method of relaying out London, the vast expense would tax even a nation's wealth, and it would be impossible for any municipality to carry it out.

Attention is constantly drawn to the Ring Strasse of Vienna, the Unter den Linden of Berlin, and the Boulevards of Paris, and the suggestion is more or less given to the minds of those who do not know that these cities consist of a series of great streets and boulevards. Such is not the case, for practically outside the streets mentioned these cities consist of narrow irregular streets, in an infinitely worse sanitary condition than those of London.

I do not think the average of narrow streets in London, proportionate to its size, is anything like as high as they are in any of the cities mentioned.

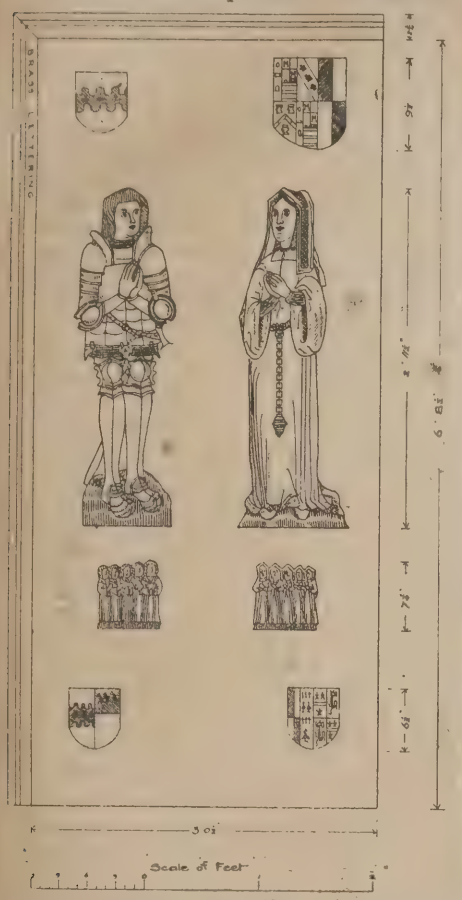
Again, it would be well to remember that though London may not be as beautiful in some of its main streets as certain of the streets in continental cities, yet at the same time there is a picturesque feeling about many of the streets of London which appeals, I believe, to the great body of the British public and its home-like appearance is appreciated by them in a way which no great straight new thoroughfare would.

I am of opinion that the London County Council in the question of improvements has done decidedly well of late years; and while I do not agree with all that is proposed, yet I do not think that the Council has carried out its schemes of improvement without giving full consideration to the effect upon London as a whole. I do not disagree with the idea which has been carried out for obtaining designs for the new street, but I think that the instructions were drawn with insufficient consideration.

The necessity in dealing with a business street like the Strand was that the designs should be made for the accommodation of business premises, not for a public building or monument. Great Classic blocks may be beautiful, but in the Strand, if they are erected, they will be practically useless from a business point of view.

Buildings such as are proposed by the designs have not sufficient light for their use as ordinary offices and are absolutely unsuited and impossible for shops, and to erect them with three great floors, in a building at least eighty feet in height, instead of seven, is so uneconomical that if such restrictions are imposed it will not only hamper the letting of the land but make it absolutely impossible to deal with it upon anything like commercial terms, or may even prevent it being dealt with at all. The Strand is a street of shops and offices, and it would be quite out of reason to expect anyone to erect buildings in which it was utterly impossible to carry on a shop business, and to erect offices of dimensions suitable only to the principal rooms and halls of the Foreign Office.

Desirable as it is to see the corporations of our great cities consulting the profession on the elevations to its new streets and improvements, it must be remembered that such consultations can, on the one side, be only of use when the corporation clearly define the purposes for which the street is to be used, and will only be asked in the future if architects will mix some common-sense with their suggestions, and design buildings not only architectural but suitable for the purpose and position.



There are at the present moment in the provincial cities and boroughs, and particularly in London, many opportunities for the profession which should provide openings for proving, from an artistic and constructive point of view, that the profession is not deteriorating but making solid advance. The many improvements and the opening of good streets must necessarily provide sites for buildings; and the increasing necessity for wider streets must in itself give opportunity to the architect for a better illustration of his art than at present is obtained in the narrow thoroughfares of many of our cities.

WOOTTON WAWEN CHURCH, FROM THE CHANTRY CHAPEL, LOOKING NORTH.

Subways.

There is another matter with which I would like to deal, which in my opinion, particularly in this crowded city of London, is of such immediate and vital importance that attention

BRASS TO JOHN AND ANNA HAREWELL AND FAMILY. MEASURED AND DRAWN BY C. M. C. ARMSTRONG.

should be drawn to it and it should occupy a prominent position in the work which the new municipalities ought immediately to take in hand. It is not perhaps strictly speaking, an architectural question, though it is certainly akin to it. I am alluding to the question of subways to meet the congested and ever-increasing volume of passenger and vehicular traffic which crowds and makes our public streets impassable, and the constant pulling up of the thoroughfares for pipes, wires, &c., which is so serious a loss to many, and an inconvenience to all.

I am the more induced to speak upon this subject because it is now some years past since I commenced to ventilate the question by the kindly aid of the press; and while much attention was then given to it, nothing has been done which substantially deals with the question. I have attempted, by proposing resolutions in the London County Council, to bring the question into a prominent position, and into what might be called the region of practical politics; so far, however, little, as I have said, has been done. We certainly have subways in the shape of a small tunnel down some of the new streets, but as a system, or to be of any material use, they are practically non-existent.

It always appears to me that there is a vast waste of useful space in the ground under the streets and roadways. The pipes and tubes and sewers which are under them scattered about all over the surface would occupy an extremely small space if all were brought together into a convenient subway; it cannot be argued that it is necessary for them to occupy the whole surface of the road or to occupy it even to such an extent as to prevent or interfere with any thorough scheme of subways.

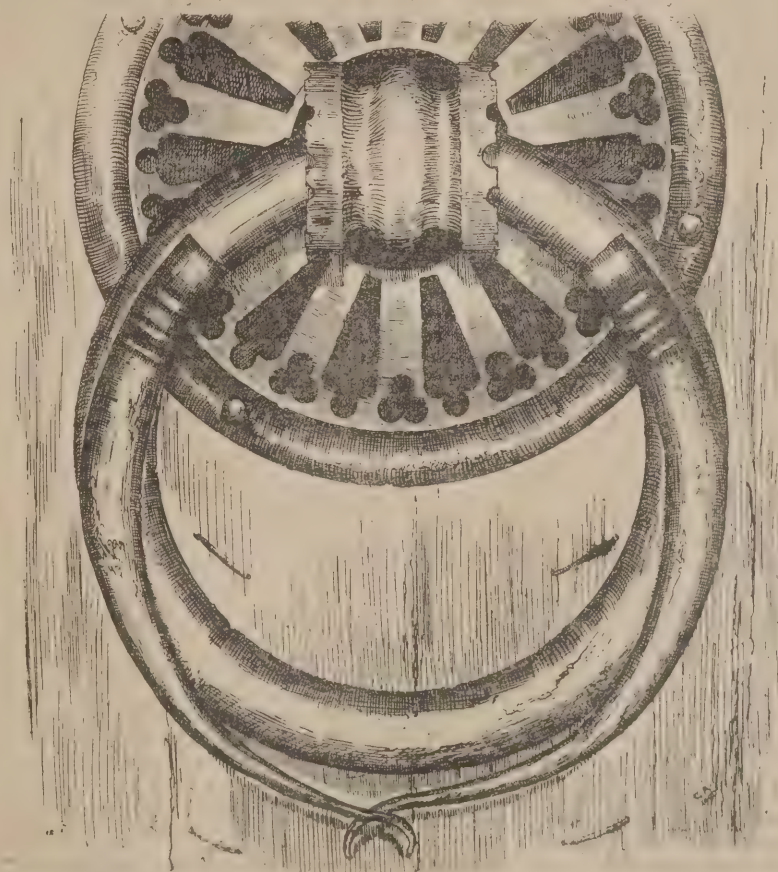
The method of dealing with subways seems to me to be by excavating the whole of the ground between the houses on either side of the road to a sufficient depth and then arching over to the road level. Such space as is now allowed for vaults would still be allowed and would belong to the houses on each side of the road, and there would be a still further amount of cellarage which could be let at fairly remunerative rents, particularly as the work of construction would be carried out at the low rate of interest which is paid by a public body.

There would remain space for one or two footways (according to the width of the street) down which the public could pass, much to its personal safety and convenience, particularly in crowded thoroughfares. There is also no reason why, where space admits, provision should not be made for a special track for cyclists. The middle portion of the subway would be retained as a tunnel, in which all the various pipes and tubes belonging to water, gas, electric, hydraulic and other companies could be laid. Under it the sewer, with the necessary manholes, &c., for entering.

There may be, and necessarily would be, difficulties in carrying out such a scheme of subways, but this would be compensated for by the many advantages which would be gained to the public when they were once constructed. Apart from those advantages which are obvious from the description I have already given, I would point out that there being in the arch a solid concrete foundation upon which the road and pavements would be laid, there would be no such thing as the sinking and giving way of portions of the road surface, and as a further consequence, and because it would not be constantly torn up, the road would wear more evenly and last for a much longer period.

Another advantage would be in the fact that whenever it became necessary to relay the road the inconvenience would be extremely slight, inasmuch as it would merely mean the taking up of the old cubes or blocks and the immediate re-laying of the new, a matter which could be performed in small sections and with the smallest amount of inconvenience to the traffic and to the business carried on by the occupants of the street. At present the loss to the shopkeepers and owners of businesses on roads which are constantly up, and partially if not wholly closed, is a very serious matter of ever-growing importance. I do not suggest that the system of subways in a great city like London could be carried out in every street at once, but certainly the leading thoroughfares might reasonably be dealt with without delay.

As a matter of fact, the saving of the very expensive methods which have now to be adopted in not only laying but in repairing tubes and wires under the ground would be saved, and so the great monopolies benefited to such an extent as to make it well worth their while to pay a fair rental for the use of the subway. The cost of attention to their tubes, &c., would be merely nominal to the various companies as compared with what it is at present, while they could deal with them at once in a subway instead of having the delays, risks and expenses of taking up the street.



It is the case that in some of the leading thoroughfares there are, under the surface of the road, over thirty different pipes and tubes of which only a portion are what might be called alive or in use, as, rather than take up an old pipe, often enough it is abandoned and left under the road, and a new tube or main laid down.

To sum up the advantages

in constructing a comprehensive scheme of subways, there is not only the fact that the probable rentals obtained from the various companies occupying them with their tubes, pipes, and from the cellarage, would be sufficient to pay a good interest on the outlay, but the roads would last longer, the public would be rarely inconvenienced—if at all—by any taking up and relaying of roads, and all the powers of the numerous companies so harassing and difficult for a public authority to deal with, and by which they can and do constantly pull roads up would be done away with, and the expense incidental to the superintendence, &c., of all these pullings up and relayings would be saved to the public authority, and hence to the public rates.

Lastly, but not least, the inconvenience to the public and the loss to business would become things of the past. For these reasons I believe this is one of the subjects which should be strongly commended to the attention not only of the London County Council as the central authority, but also to the new municipalities, as while rates may increase from many causes under the new authority, by this corresponding advantages would be given, even if a valuable source of income is not provided, as I believe would be the case.

I trust in calling your attention to this subject I am not going too far outside my province as the President of your Society; but it is a matter of serious importance to the public and

WROUGHT-IRON SCUTCHEON AND RING, NORTH DOOR. DRAWN BY C. M. C. ARMSTRONG.

so closely allied to the work we have to do that I hope I may be forgiven the transgression, if it is one. In conclusion, I would express my hope that the Society will continue its prosperous career, and that its sphere of usefulness will be, by the energy of its members and those whom we hope will join, considerably increased. I particularly wish to express to the members of the Society the great debt they are under, for the successful working, to the honorary secretary, Mr. Ellis Marsland, and to the secretary, Mr. C. McArthur Butler.

LONDON COUNTY COUNCIL.

Housing—Electric Tramways—Subways—The Embankment — Holborn-Strand Designs — Female Sanitary Inspectors—River Wall for Wandsworth Park—Widening of King Street, Hammersmith—Leicester Square Fountain—Regent's Canal—Camberwell Workhouse Extensions.

AT last week's meeting of the Council the General Purposes Committee recommended:—(*a*) That, with a view to the reorganisation of the housing work of the Council and in order to secure more efficient and economical administration, a Housing Department be formed. (*b*) That the head of the department be styled "Housing Manager." (*c*) That a housing manager be appointed at a salary of £800 per annum. (*d*) That the duties of the housing manager be as follows: (i.) To be responsible for the charge and control of all estates and buildings laid out and erected by the Council for the housing of the working classes, including all lettings, small repairs, and the collection of rents subject to the supervision of the comptroller as at present; (ii.) to advise the committee as to the most suitable class of buildings to be erected, and generally on the whole question of dealing with the housing of the working classes; (iii.) to advise as to the rents ruling in the neighbourhood of any particular scheme, and as to the amount which should be set apart annually for necessary repairs, and generally to prepare the estimates as to the financial effect after obtaining all necessary information from the various departments; and (iv.) to search for and advise as to sites suitable for the erection of working-class dwellings. (*e*) That the valuation of land and the acquisition of property in connection with housing schemes do remain in the hands of the Council's valuer. (*f*) That the architect do prepare the designs for new buildings as directed by the Housing Committee, do supervise their erection, do advise thereon, and be responsible for the main structural repairs required to the dwellings. (*g*) That the duties of the medical officer of health in connection with the housing work do remain unchanged. After discussion the recommendations were agreed to.

Mr. Baker moved: "That, in view of the desirableness of no longer withholding from North and East London the advantages of electric tramway traction, and of the importance of providing a complete and united system of electric tramway intercommunication between the different parts of the metropolis, the Highways Committee be instructed to ascertain from the North Metropolitan Tramways Company at what price they will surrender the lease now held from the Council, which expires in July, 1910." This was carried.

Mr. Parker moved: "That, to mark the importance of the addition to the civic interests of the metropolis by the creation of the new Borough Councils, it be referred to the General Purposes Committee to consider the best manner of bringing before those councils the imperative necessity of making subways under, at least, all the leading thoroughfares of the metropolis to contain all the gas and water pipes, and telephone and telegraph wires; and, if necessary, to summon a conference to formulate some comprehensive scheme for remedying the scandalous and ever-increasing inconvenience to pedestrian, omnibus, and mercantile traffic caused by the constant tearing up of the footways and roadways for the purpose of inserting or removing the pipes, wires, &c., above referred to." While Mr. Parker was speaking to the motion the Council was counted out.

The Highways Committee reported that they had had before them an application from the New River Company for permission to lay a 30-in. water main under the carriageway of the Victoria Embankment from Blackfriars Bridge to a point opposite the foot of Northumberland Aveuue. In the ordinary course they would have suggested that the company should be required to lay the main in the Embankment subway. They were, however, informed that the subway was already too full to allow the main to be placed there, except for a very short distance; and, that being so, they thought that the company's request should be acceded to, subject to certain conditions. An amendment was moved, but negatived, in favour of obtaining some payment from the New River Company for the use of the roadway.

The Improvements Committee reported that upon opening the sealed envelopes containing the names of the architects of the elevations of the buildings for the new part of the Strand they found that they were as follows:—Mr. Ernest Runtz (No. 17), Mr. Edward W. Mountford (19), Mr. Mervyn Macartney (20), Mr. Reginald Blomfield (21), Mr. Ernest George (23), Mr. Henry T. Hare (26), Mr. W. Flockhart (27), and Mr. Leonard Stokes (29). Mr. Shaw Lefevre asked the chairman of the committee whether the architect and the valuer would be instructed to report on Sir Frederick Bramwell's suggestion for an upper row of shops in the new street on the lines of Chester "Rows." He did not say he agreed that the scheme was practicable, but, coming from such a man of eminence, and, considering the great public interest taken, it would be very satisfactory to obtain expert opinion upon the matter. Dr. White (Mayor of Lambeth) asked if any use would be made of the plans. Dr. Longstaffe said the matter referred to by Mr. Shaw Lefevre would be considered by the Council. With reference to Dr. White's question, he was not in a position to give an answer. The Improvements Committee were now in communication with the Sites Committee.

The Council, after some discussion, agreed to pay half the salaries of those female sanitary inspectors who, in addition to their other duties, would use such opportunities as presented themselves of inculcating habits of cleanliness and the best methods of utilising food.

A report recommending the acceptance of a tender for the construction of a river wall for Wandsworth Park at a cost of £16,250 led to considerable dissatisfaction among the members. It was stated that the original estimate amounted to £6,000. Being impressed with objections of Lord Meath and others as to not only the cost of the wall but the wall itself, Mr. Davies decided to withdraw the report for a time.

The Council agreed to contribute £5,918 towards the cost of widening King Street, Hammersmith.

The Parks Committee recommended: "That the Council do sanction an expenditure of £250 for carrying out certain alterations and repairs to the Shakespeare fountain in Leicester Square Garden, including the taking down and re-erection of the fountain on a new foundation, the formation of a proper chamber for the accommodation of the water fittings, and the construction of a manhole and subway to lead to the same, and the execution of such repairs, cleaning, &c., as may be necessary; and also do authorise the Parks Committee to invite tenders from selected firms and to enter into any necessary contract in the matter." This was agreed to.

The Public Health Committee submitted a lengthy report relating to the nuisance alleged to arise from the condition of the water in the Regent's Canal, between Chalk Farm Road and the Cumberland basin. Dr. W. J. Collins said it was time serious consideration should be given to whether or no a stagnant open sewer, such as the canal, should any longer be allowed to menace the sanitary condition of London. Several members also protested against the state of the canal, and eventually it was decided to send a letter to the councils of metropolitan boroughs asking them to keep the canal under careful observation.

Upon the recommendation of the Finance Committee, it was agreed to lend the Camberwell Guardians £2,550 for alterations and additions to the workhouse.

Builders' Notes.

The Wandsworth Borough Council had a heated argument last week over a proposal to exclude builders from the Highways Committee, a motion to that effect being rejected upon a division by 32 to 22.

The Works of Messrs. Raworth and Allen, joiners and builders, at the junction of Bower and Strawberrydale Roads, Harrogate, were completely destroyed by fire last week. The damage is estimated at £3,000, and is only partially covered by insurance.

Mr. Augustus Lewis, contractor, of Cardiff, died recently at the age of 61 years. Mr. Lewis was born at Kingswood, near Bristol, but came to Cardiff in early life. After some years he started business as a contractor, and erected several large buildings, including the Grand Theatre and Grand Hotel. In conjunction with his brother, Mr. Robert Lewis, he was also contractor for the building of many places of Divine worship in the town.

Fireproofing at the Building Trades' Exhibition, 1901.—An important feature of the coming Building Trades' Exhibition will be a special section devoted solely to fire-resisting materials, methods of construction, and appliances. This section, which will form the first collective exhibit of its kind, is to be organised by the executive of the British Fire Prevention Committee, whose members fully recognise the importance which the trade aspect of fireproofing has assumed since the Cripplegate fire, and are anxious to obtain for this trade the importance and recognition of an independent department of building construction. A separate hall has been set aside for the fireproofing exhibits, and the space in this hall has been very carefully set out, so that there will be the possibility of a thoroughly practical display on the part of the firms interested. A special sub-committee is being formed by Mr. Edwin O. Sachs, the chairman, in conjunction with Mr. Frederick R. Farrow, who presides over the commercial section of the British Fire Prevention Committee, and it is proposed to issue invitations to the leading authorities on fire protection, &c., throughout the country, to participate, by attendance and otherwise, in the Exhibition in question. The whole of the business arrangements will be in the hands of Mr. Montgomery, of Essex Street, Strand, the organiser of the Building Trades' Exhibition, but all questions of scientific interest and practical display will be in the hands of the Fire Prevention Committee, with the view of making the section thoroughly useful to the architectural, surveying, and engineering professions, as well as to the local authorities and insurance companies. The Fire Prevention Committee will themselves be exhibiting a model of their testing station, reports, photographs, &c., and will prepare a special technical catalogue and analysis of the section in question.

Builders' Benevolent Institution.—The fifty-third annual dinner of this institution was held on Thursday last in the hall of the Carpenters' Company, London Wall. Mr. John Greenwood, C.C. (president), occupied the chair, and the company numbered altogether about 140. The president stated that the charity was founded in 1847, since which time there had been 289 pensioners elected, the present number being 46. Of these the men received £39 and the women £27 a year. New annual subscribers were urgently needed to take the place of those who had been removed by death. The institution depended entirely on the liberality of the members of the building trade, who might be sure that whatever they subscribed would be thankfully received and faithfully applied. Major Brutton (secretary) read the list of donations, which showed a total of £720. Of this amount the president's list represented £574, his own subscription being £105. Major Brutton was presented with a testimonial, together with a cheque for £160, by upwards of 200 subscribers, in recognition of twenty-five years' faithful service as secretary of the Institution.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Widening a Bridge.

SHIPTON.—ASSISTANT writes: "It is proposed to widen the bridge as shown on the accompanying sketch (not reproduced). I shall be glad to know if you consider the retaining walls (shown in section) to be of sufficient strength, also the girders, the greatest live load being that of a steam roller weighing 13 tons."

The tracing enclosed with query is very rough. The new girders appear to be 30ft., 25ft., 22ft., and 20ft. span respectively, placed closer as the span increases, but, say, 5ft. apart. They should therefore not be less than 15in. deep. Assuming that they have to carry a dead load of 1½cwt. per ft. super. and a live load of the same amount, the load on the 25ft. span will be 18·75 tons, requiring 15 × 6 × 59lbs. rolled steel joists. Between these should be placed transversely 4 × 3 × 12lbs. rolled steel joists 4ft. 6in. apart, embedded in the cement-concrete and level with underside. The retaining wall should be 4ft. 6in. thick at bottom and batter 3in. per ft. of height. The back may be stepped in 4½in. set-offs to a thickness of 2ft. at top. If the shale has a dip towards the railway the wall on that side might batter 4½in. per ft. of height.

HENRY ADAMS.

Cements.

COLWYN, N. WALES.—CONTRACTOR writes "What are artificial cements and natural cements; what are the usual tests for Portland cement; for what purpose is silver sand used in combination with Portland cement?"

Portland cement, slag, Robinson's, and similar cements are artificial cements. Roman cement, plaster-of-Paris, and similar cements are natural cements. The term natural is only applied to those cements which are made direct from a mineral by burning and grinding, and without the addition of other materials. The usual tests for Portland cement are colour, weight, fineness, tensile and transverse strengths. There are other tests which are sometimes used by manufacturers for their own satisfaction before sending the cement to the users. Silver sand is used with Portland cement to give the fining coat a close and uniform texture, also to impart a white, or a silver-grey, colour to the finished surface.

W. MILLAR.

Movable Floors for Swimming Baths.

PRESTON. NOUVEAU writes: "I should be glad to know how to construct a movable wood floor over a swimming bath 30ft. wide, to be used as a gymnasium and entertainment hall during the winter season. Can you give me the names of any baths where this has already been done, and is the scheme a success as regards rigidity of construction and easy removal? Are there any good books published on swimming baths?"

We have constructed movable floors to the baths at Hampstead and elsewhere, and they have always proved satisfactory as regards rigidity of construction and easy removal. The usual arrangement is to have rows of longitudinal bearers, framed in sections, in the pond of the bath, with stout flooring boards across, the bearers being placed about 5ft. apart.

SPALDING AND SPALDING.

Mr. Saxon Snell's article on public baths and washhouses, published in our issue for March 28th last, will doubtless be of use to our correspondent. "Public Baths and Washhouses," by R. O. Allsop, is a book which may be obtained from Mr. B. T. Batsford, 94 High Holborn, for 5s. (postage 3d.).

Book on Specifications, Quantities and Prices.

CARDIFF.—S. M. writes: "Kindly mention a good book on specifications, quantities, and the price of same."

"Specification: No. 4," price 5s., which can be obtained from these offices.

Duties of a Clerk of Works.

FULHAM, S.W.—M. A. B. writes: "Is there any book published that gives instructions as to the duties of a clerk of works?"

"The Conduct of Building Work and the Duties of a Clerk of Works," by J. Leaning. Price 2s. Published by Mr. B. T. Batsford, 94 High Holborn, W.C.

Strength of Balcony.

PRESTON, LANCS.—NOUVEAU writes: "I should be glad to know what would be the safe live load per sq. ft. to allow for the balcony shown in the accompanying sketch. The balcony is to carry the switchboard in an electric-light station, and the switchboard will be fixed in the centre. The concrete floor is 8in. thick and composed of brickbats 2in. mesh and 4 to 1, finished off with 1in. rendering to floor. Owing to the level of the floor being fixed wrongly the concrete has worked out thicker than was intended, and has, therefore, brought more weight on the cantilevers, although very little vibration is felt when standing on the points of the cantilevers and jumping on them."

The concrete and ironwork together will weigh about ¾ cwt. per ft. sup., and the balcony will be safe with a live load of ¾ cwt. per ft. sup. in addition to the dead load. The weight of switchboard, according to the weight and space occupied, will reduce the above estimate.

HENRY ADAMS.

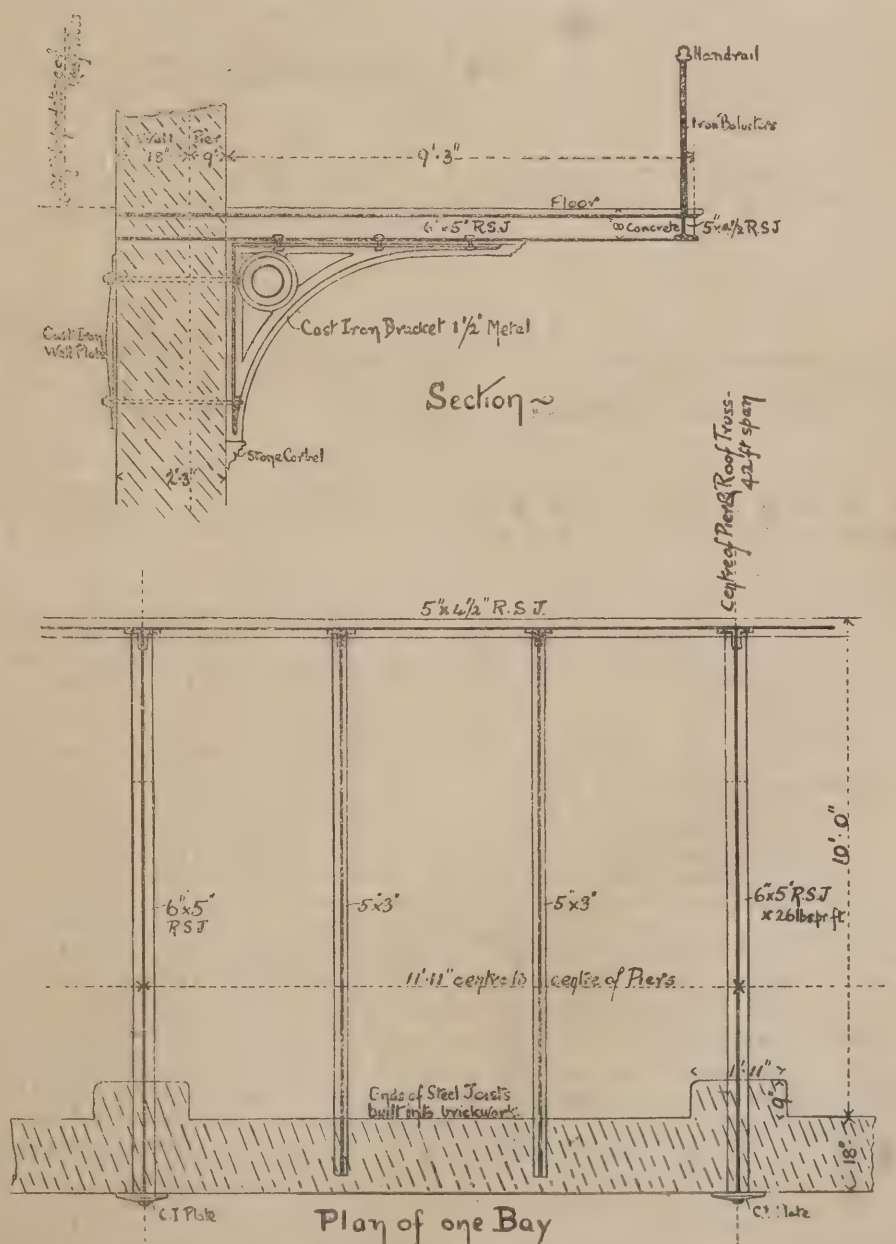
Examinations in Geometry.

BRECHIN, N.B.—H. A. F. writes: "Please say how much geometry is necesssry for me to prepare for the advanced examination in that subject. I am using Angell's text-book; if you could name the chapters in that book required to be learned I should feel obliged."

The whole of Angell's larger book, in two volumes, in addition to his small book, should be thoroughly mastered, and not merely learned.

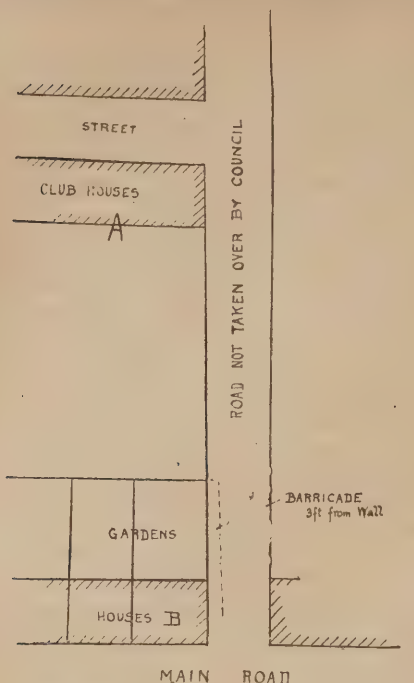
G. A. T. M.

Appointments under Colonial Governments.



SOUTHSEA.—J. H. M. writes: "To whom should I apply for information about appointments in the Civil Engineering, Surveying, and Architectural Departments of the Governments of Canada, India and Australia?"

Write to the Agents-General for Canada, Victoria, New South Wales, Queensland, and Western Australia, all of whom have their offices in Victoria Street, Westminster, S.W., and to the Secretary of State for India, Whitehall, S.W.



G. A. T. M.

Right to Erect a Barricade.

HENGOED, CARDIFF.—P. V. J. writes: "Referring to the accompanying sketch, a building club built houses as shown at A. The private road from the main road to the entrance of the

STRENGTH OF BALCONY.

RIGHT TO ERECT BARRICADE.

street in front of the houses was in a bad state of repair, and in order to increase the value of the houses the club, with a little pecuniary aid, decided to repair the road; but as soon as this was commenced the owner of the house marked B (on lease from the estate) abutting on the main road, put up the barricade shown, and says he owns three feet outside his wall, although it is a known fact that for thirty years past the road has been open to the public. Can the owner be compelled to take down the barricade?"

It appears that the owner of the house in question has allowed the public to acquire a right over the ground which he claims, and that he has now no right to enclose it.

G. H. B.

SCIENTIFIC SOCIETIES.

IN dealing with "The Origin, Development, and Aims of our Scientific Societies" at the opening meeting on Wednesday last of the 147th session of the Society of Arts, Sir John Evans, F.R.S., the new chairman of the Council, admitted that the subject was a large one, and that it would be impossible to enter into details with regard to its almost innumerable ramifications. Beginning with very ancient history, he showed that the Academia in Athens and the museum founded by Ptolemy Philadelphus in Alexandria were much of the nature of scientific societies, though no doubt mainly educational. In England no learned society received the Royal Charter before 1662, when the Royal Society was incorporated by Charles II., but it had been instituted in 1660. Fifteen years previously a society of friends of experimental philosophy had been formed in London, where they met weekly. About the year 1572 "divers gentlemen of London, studious in antiquities, framed themselves into a College or Society of Antiquaries." The honour of this foundation was due to that munificent patron of letters and learned men, Archbishop Parker. In 1589 they decided to apply to Queen Elizabeth for a charter and for some public building where they might assemble. It is uncertain whether the petition was presented or not, but the Queen seems to have given the society her countenance, and it flourished until the reign of James I., who for some reason dissolved it in 1604. The society remained dormant until 1707, was reconstituted in 1718, and received its charter in 1751 from George II., who thereupon declared himself its founder.

Having traced the inception of the two oldest of our learned societies, Sir John Evans proceeded to indicate the proper aims and objects of a learned society, and then reverted to the history of the Royal Society and other institutions in the eighteenth century. He went on to show how later societies were derived directly or indirectly from the two older ones, with which the Society for the Encouragement of Arts, Manufactures, and Commerce, founded in 1754, was associated as a third parent. For the Society of Arts it was claimed that at least as numerous an offspring could be cited as for its two elder sisters. Even the Science and Art Department at South Kensington might be included, as that institution grew out of the 1851 Exhibition, which was organised by the Society of Arts. The chairman went on to show what good work the society had done in promoting useful inventions and educational movements, and for the advancement of art. Perhaps the first public exhibition of pictures was held in its rooms in 1760, from which sprang the Royal Academy. In conclusion Sir John Evans referred to what might be termed the societies representing the philosophico-historical sciences as distinct from mathematical, physical, and biological sciences.

OUR NEEDS AND PROGRESS IN THE ARTS.

IN the course of a lecture with the above title, delivered at Leeds on Thursday last, Mr. Frederick Wedmore said that real artistic progress was scarcely a matter that lay within our command. Education could not compass it, and neither schools nor Universities could bring it about. The finest works of art, in painting, sculpture, music, or literature, came at no one's beck and call; and all that higher education could do was to make men readier to receive a beautiful production when it arrived. But, of course—and in handicraft and applied art especially—there was such a thing as a general improvement in taste, and within the last twenty years great improvement had had to be noted, and in rooms of many styles, expensive and inexpensive, it was possible now to be surrounded with tasteful form and attractive colour. Exhibitions of arts and crafts, said Mr. Wedmore, had done something, and they had done most when they had not been narrow. If they had decided that French eighteenth-century furniture was of a "bad period," taste and fashion had gone beyond them; the style of Louis XV., in France, was now firmly rooted in England as pure and good. Respecting our needs in art, one of the first of them—especially amongst artists—was the absolute avoidance of that narrowness which resulted in condemning great things only for want of understanding them. The word "artistic" was used too commonly and falsely; to some people, for instance, a curtain was an "art curtain" if only it was of sage green colour, and absorbed all the light. A door-mat was the only thing in household furniture which did not yet put forth its preposterous claim to be "artistic." Nevertheless, with all this silly prating about art, by those who had not got the root of the matter in them, the lecturer did really believe that there was some progress in taste—some added sensibility to lovely colour and line. Women's dress showed it. In the decorative arts there was great need not to extol too much the interesting and curious school of Japan, which happened of late years to have been popular. We were caught by mere novelty; and now that the art of Japan, and its principles of ornament, were novel no longer, there was perhaps a greater chance even amongst most ordinary people for the appreciation of the Renaissance. What—despite its admirable ingenuity and ready effectiveness—was Japanese ornament by the side of Inigo Jones, Holbein, and Aldegrever? That the fine art of engraving had fallen into disuse, was a lamentable fact the lecturer had to glance at. Some compensation, perhaps, lay in the appreciation of original etching; but yet no one art could fulfil the functions of another. Photography was a craft now both popular and ingenious, but it must not be suffered to stifle the life out of an art that nothing of its own could replace.

Quarry Notes.

Mr. R. R. Jones, late manager of the Pa dreiniog Quarry, Bethesda, has been appoin general manager of the Foxdale Slate Quarr Isle of Man.

Mr. W. C. Bryant, of 42 and 43 Main Stre Birmingham, having given up the represen tion of the Maglona Quarries, Limited, inte to trade in enamelled-slate chimney pieces his own account.

The Largest Block of Stone ever blasted Derbyshire was recently raised from the Asho quarry. It measured 33ft. long by 31ft. w and 23ft. deep, and contained upwards 23,500 cubic feet.

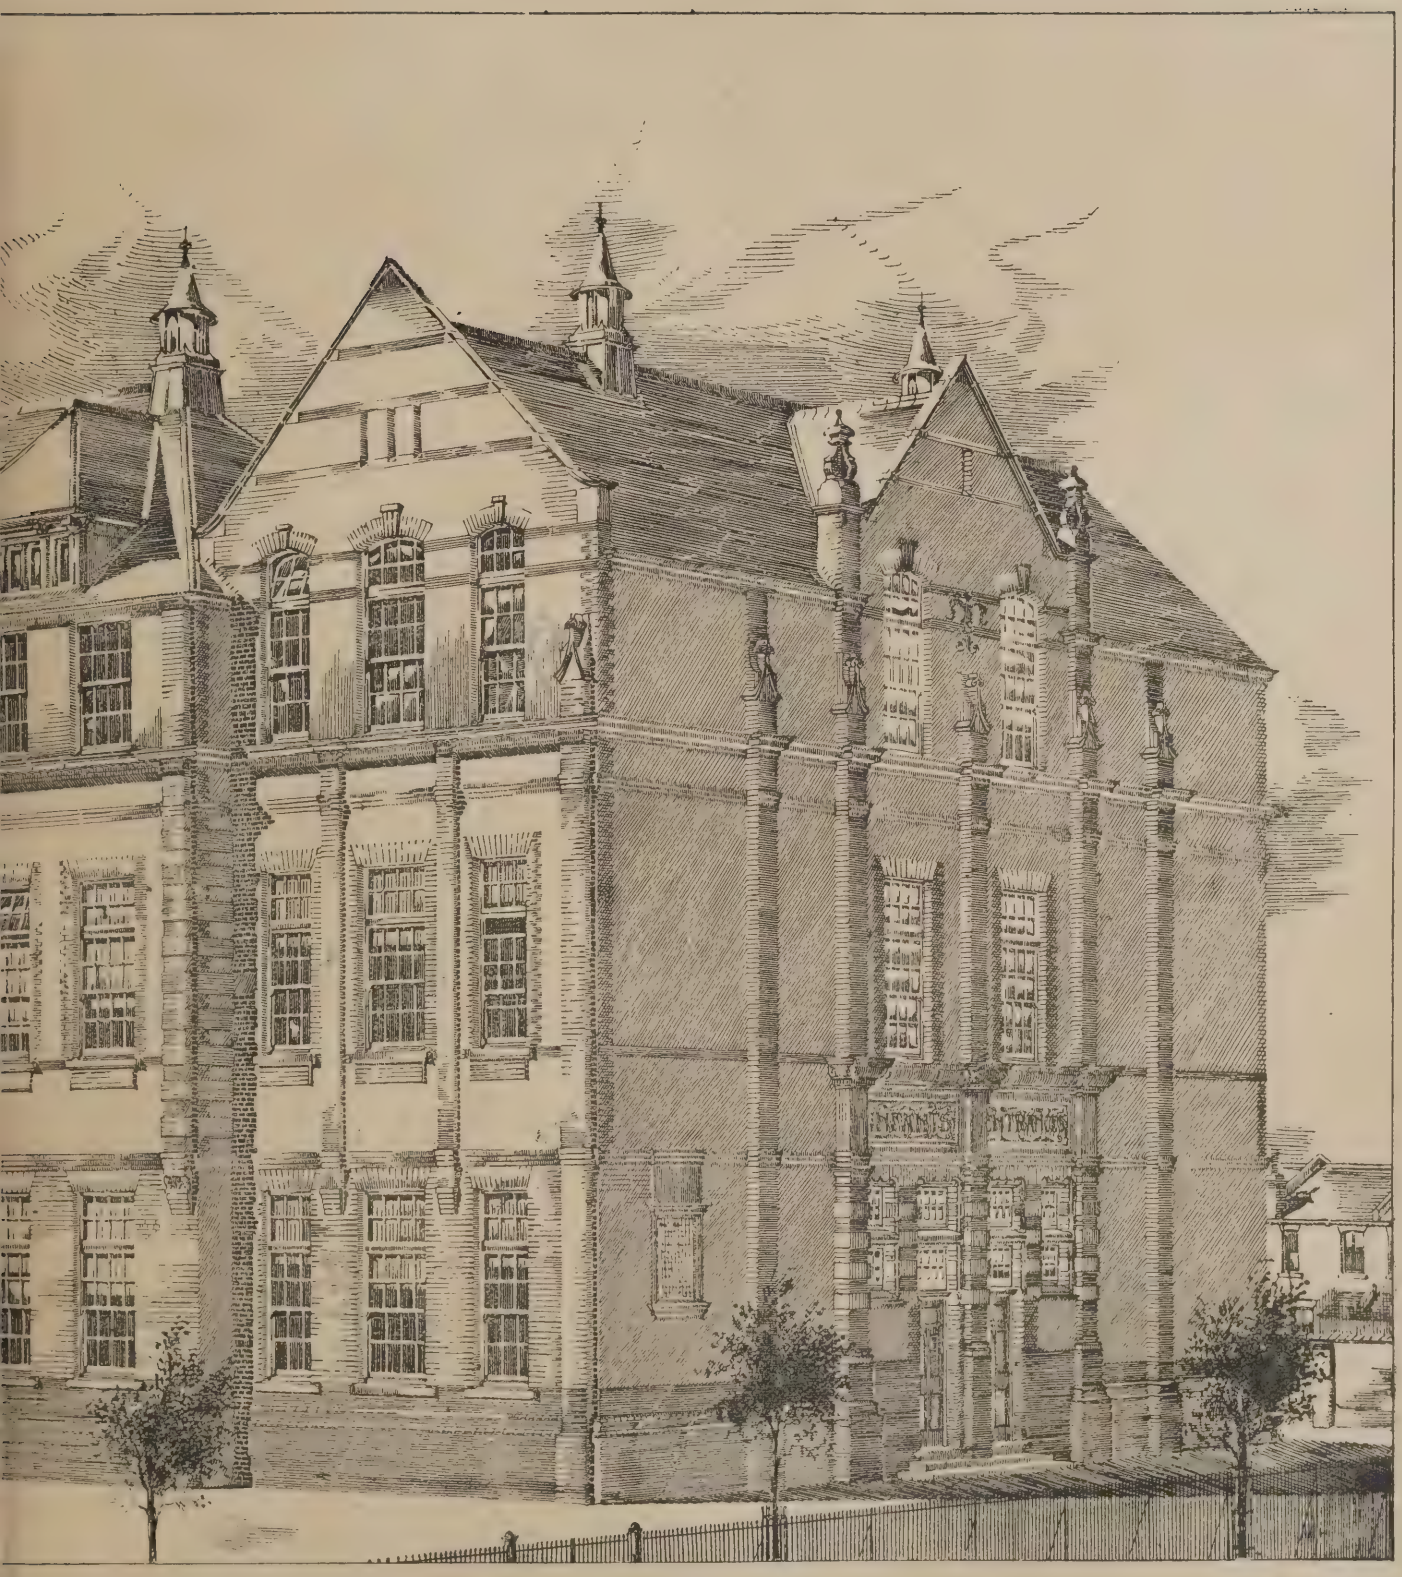
A New Grey Granite, known as Craiglart about to be placed on the market. It is scribed as light grey in colour and of cl texture; it can be quarried in large blocks, a if all that is said of it be true, it is likely prove a valuable addition to the trade.

The Quarry at Crelly has been reopened. has been worked on two previous occasic but owing to the unsuitable nature of the st was abandoned. The extra amount wh must be spent on the quarry at Carnmenellis ensure a further supply of stone was conside a reasonable cause for making another atten at Crelly, hence the activity now displayed the workmen at the foot of Crelly Hill.

The Devon Slate Quarries, Limited, a compa which was some months ago formed for purpose of acquiring and working the sl quarries at South Larcombe, New Larcon and Totnes, is making very satisfactory p gress. The slate proves to be of an excell quality, and commands a sale to the full ext of its production. The registered offices of t company are at 25 Victoria Street, We minster, S.W.

The Slate Trade seems to be somewhat pressed. At Portmadoc stocking tends lower the prices. For some kinds of sl there is a fairly good demand; the mid sizes of the best and second qualities are s at Carnarvon almost as quickly as they can produced. Labour is scarce, some of t quarries are not in working order, and there a lock-out at Lord Penryhn's quarries, whe the quarrymen, numbering 4,000, removed th tools on Saturday.

Marble Tile Pavements are constantly i creasing in favour in England and on t Continent. According to the "Bankok Time the head priest at Wat Mahatat, in Mua Pitsanuloke, is also about to pave the floor the temple there with marble. He has received large number of subscriptions, including one 2,000 ticals from Queen Phra Boromarac Devi.



The Llanberis Slate Quarries, the secor largest in the kingdom, are about to mal great developments. A large area of grani rock in the mountain side, known as t Dyffryn Rock, which has prevented much goo slate from being worked, is to be removed at cost of between £40,000 and £70,000. Mo than 400 extra quarrymen will be needed f the work, and it is quite likely that many the locked-out miners from the rival Penrhy quarries at Bethesda will seize the opportuni for employment.

The Architectural Granite Trade is very slo although several large-sized contracts ha been recently placed. The demand for ra material, however, remains keen, and the in ports from foreign ports will no doubt conside ably increase. The Aberdeen granite firm who have for many years imported abo 10,000 tons of foreign granite, mostly fro Norway and Sweden, are trying the exper ment of supplementing the supply by bringin Irish granite from County Donegal, which ha literally miles of granite formation waiting t be developed. If the experiment proves financial success, we may expect to see shi ments made direct to London and other larg centres.

Bricks and Mortar.

APHORISM FOR THE WEEK.

"Seraphs share with thee
Knowledge: But Art, O man, is thine alone!"
SCHILLER.

Our Plates. We give this week Mr. Flockhart's designs, numbered 27, for the Holborn-Strand buildings. Bessborough Road School was erected by the Little Ilford School Board and was opened in June last. It is built to accommodate 1,709 children, namely, 529 infants, 540 girls, and 540 boys. The site comprises an acre and a half, and there is a caretaker's cottage in the playground. The total cost was £19,850. Mr. S. Jackson, of 65 Fenchurch Street, E.C., was the architect, and Messrs. Gregar and Son, of Stratford, E., were the builders.

Cripplegate's "Four Shoppes." The block of buildings in Cripplegate known as the "Four Shoppes," which is parochial property, has been sold to the Corporation for the respectable sum of about £19,000, and is shortly to be demolished. No other buildings are to be erected on the site, but the ground will become part and parcel of the churchyard. Consequently, says the "City Press," the section of the ancient church of St. Giles which is now hidden will be thrown open to public view, as it was about three or four hundred years ago. "The entrance gateway to the churchyard, which is part of the block, and which is looked upon as one of the finest and most unique specimens of early architecture extant, is, we are glad to say, not to be included in the demolition scheme as a permanent removal. The Corporation propose to simply set it back, and allow it to remain as the entrance to the church path. There are two blank windows on the side of the church, and Mr. Joseph Mann and other prominent parishioners will set a scheme afoot at the next vestry meeting to open up the windows and place in one a memorial of the great fire of three years ago, when, though about half the parish was burnt down, the church again escaped. The fire-station facing the entrance to Jewin Street is nearing completion, and the authorities recognise the fact that some provision must be made to facilitate the brigade getting smartly away. This part of the thoroughfare is characterised by constant stagnation in the traffic, and it has been suggested that, when the demolition of the buildings mentioned takes place, a way from Fore Street into Jewin Street should be cut through the block of buildings on the east side. If this is done, the traffic will be greatly relieved."

Sculptured Crosses. Lecturing recently at Barrow on sculptured crosses dating from 670 to 1050 A.D., Mr. W. G. Collingwood, M.A., said that some of them were Anglo-Saxon, while others were Irish or by Norse settlers who came from Ireland. He next described those to be found round the coast, dealing particularly with those in West Cumberland (chiefly Norse), the Gosforth Cross, and at places like Cross Canonby, Dearham, Aspatria, and all round where the old Roman road went. From Ravenglass round the coast to Carlisle the Norse from Ireland settled and left one type of cross. At Bewcastle, on the border, there is the old Anglican cross, a monument to King Alcfrith, carved by workmen hired probably by St. Wilfrith. Going up the Eden Valley one strikes the Roman road again and gets on the track of the much later Norse and Danish settlers. At Penrith there is the Giant's Grave. Then at Halton, on the Lune, one finds very late crosses with an interesting story of Siguard, the mythological legend of the Norsemen, a Christian cross, but with heathen myths upon it. This series ends at Heysham, where there is the old arch of a Saxon chapel, and gravestones both of the earlier Saxon and later Danish type.

Nothing New under the Sun. It is probable that Sir Frederick Bramwell considered he was distinctly original when he proposed to construct footways at the first-floor level, but the late Mr. Charles Henman, F.R.I.B.A., and Sir Martin Conway appeared to have forestalled him. The former exhibited at the Paris International Exhibition in 1855 a design showing shops at the first-floor level with a covered footway fronting them, connected by bridges at the intersection of the side streets. He also submitted to the Royal Commision "a design for embanking the Thames," showing a roadway (at the level of that now in existence) having warehouses along its land side. Above is a second roadway at the level of the bridges, while the shops bordering this have covered footpaths in front of them. This design was exhibited at the London International Exhibition, 1862, and also at the Royal Academy. Sir Martin Conway, in March, 1895, put forward a scheme practically identical with Sir Frederick Bramwell's, though it had no immediate reference to a specific improvement. Criticising the two schemes, the "Daily Chronicle" remarks that we must remember that Sir Frederick Bramwell, though a most distinguished engineer, is not an architect, and Sir Martin Conway is chiefly famous for climbing mountains, which is a different art from designing level streets. It is interesting to note that a block of buildings now in course of erection at the corner of Shaftesbury Avenue and Vine Street (from designs by Mr. Robert J. Worley) has shops and a covered footway at the first-floor level.

Electric Lighting in Theatres. The electric light is, without doubt, the finest illuminant yet discovered, but it is remarkable to note how very recent its application for general purposes has been. At the present time almost every theatre and music-hall in London is lighted by electricity, but all this has taken place since 1881, when the Savoy Theatre was fitted throughout. Mr. D'Oyly Carte's chief trouble was to prove to the theatre-going public that there was no danger. As the "Daily News" points out, the more timid seemed to have some idea that an accident to the electric lights might involve some sort of lightning flash, while even more level-headed folk shook their heads lest the electricity might suddenly fail, and a stampede should occur in the darkness. So Mr. Carte, in order to reassure everybody, made a speech on the stage, showing how the "pilot" of the sunlight was always kept burning, so that the house could be flooded with gaslight at a moment's notice, and smashed an electric incandescent lamp with a hammer to prove there was no danger. The audience were also invited, after the representation, to see the electric lighting on the stage, where they were received by Mr. George Edwardes, who was then Mr. Carte's acting manager. The only real difficulty which Mr. D'Oyly Carte found in adopting the electric light was with the scenery, for the white electric lamps rendered necessary totally different colours to those used by scene painters for the yellow gas lights. The difficulty was, however, overcome by the skill of Mr. Henry Emden. Now, as already mentioned, almost every stage in London has the electric light, while at the opera the very scenery is henceforward to be shifted by electric power.

Spoiling an Old Street. The "Daily Graphic" states that Prince Christian has approved the plans for a volunteer drill-hall and gymnasium near Windsor Castle, and has consented to the building being dedicated to the memory of the late Prince Christian Victor. Laudable and opportune as the proposal is, there are many who will learn with regret that the Mayor and Corporation of Windsor have decided to erect the building at the expense of some of the oldest and most historic houses in the town. The site chosen is in the old street which lies between the Guildhall and the vicarage, and is well known to visitors of the Castle, facing as it does the Henry VIII. gateway. The majority of the old houses in this street were built purposely for the residences of ladies and gentlemen in attendance at the gay Court of Charles II., and an underground passage connects all the houses on the east side of the street as far as the old vicarage, and branches off from there to the Castle. This passage was closed up about forty years ago. The house in which Nell Gwyn is said to have stayed is on this side of the street, but it is more than doubtful if she really resided there. The old Town Hall, stood at the Castle end of Church Street, but was done away with when the present Guildhall was built (1789). At the opposite end of the street was the lock-up, and it was here, early in the nineteenth century, that the notorious Barthelmy was brought after his arrest at Priest's Hill, the scene of his last duel, in which he killed his antagonist, a fellow-countryman. Strong protests are being made by many of the leading residents against the contemplated defacement of this ancient street, and it has been suggested that a memorial should be got up and presented to the Town Council.

A Man who Dislikes Builders. Says a writer in the "Country Gentleman":—"With builders there is nothing to do but endure. Speech is unavailing. Very often they don't even hear it. They go about intent on one thing—the utter and complete demolition of everything old that you hold dear, in order that something new may be forthcoming which you did not really want. They are brusque, unswerving, unapproachable. . . . The real trouble is bricks and mortar. If we were content to live in wooden houses all would be well. One brick can spoil a landscape, but no quantity of accumulated logs can injure it. Indeed, a heap of logs is always appropriate, always fits itself naturally into the picture. Planks certainly are not becoming; but planks are for the most part kept indoors. . . . Now, the well-sinker is a vastly superior person. . . . He leaves very little mess, he works in a small area, and he makes no noise. Better still, he keeps himself hidden. One's only chance of seeing him is to lean over the edge of the hole and peer down. After a while, when the eyes are accustomed to the darkness, one is aware of a patient little gnome, absurdly foreshortened, filling a bucket with a spade. It is the well-sinker. At the top, with their brawny arms at ease on the windlass, are his two subordinates. . . . The men at the windlass talk and smoke and are happy; the man below toils all day. But—a strange variation upon the usual rule—it is the man below who is the master, the employer, the capitalist, and the men above who are mere labourers. . . . One well-sinker is, to my mind, worth a myriad builders."

St. Augustine's, Canterbury. Canon Routledge announces that excavations have been commenced on the site of St. Augustine's Abbey, which, it will be remembered, was purchased by subscription a few months ago to prevent its falling into the hands of unsympathetic builders. The works are being carried out under the direction and personal supervision of Canon Routledge and Mr. W. St. John Hope, and have already yielded satisfactory results. The remains of the early Saxon Chapel of St. Pancras have been uncovered, and the floor was found to be covered in places with masses of fallen Saxon masonry. A Roman pillar was found *in situ*, and portions of two others were discovered among the *débris*. The plan of the chapel as now revealed is a valuable addition to the few early Saxon plans previously known. Operations have also been commenced on the site of the great Abbey Church of SS. Peter and Paul, which is known to cover the sites of two earlier Saxon churches, one built by King Ethelbert for St. Augustine, and another raised by Eadbald. The north end of the transept was opened out, showing remains of an apsidal chapel to the east, and structures at the east end of the church have been partly unearthed, while the chapter-house and the walls of a large hall (probably the infirmary) have been traced. The work on this portion of the site will, however, have to be postponed, partly on account of the approach of winter, and partly on the score of expense, as a huge mass of earth was deposited on the site of the presbytery twenty years ago.

THE NEW COLSTON HALL.

THE new Colston Hall, Bristol, was opened yesterday. It is now some two years since competitive drawings were submitted for the restoration of this hall. The designs were then assessed by Mr. H. L. Florence, and those submitted by Messrs. F. H Jones and Cummings, London, selected. The apparent defect of the scheme, however, was the limited space available for the large orchestra and chorus and for a grand organ. The directors therefore fully considered the matter with their architects, and determined, if possible, to secure the piece of ground adjoining the organ end; this they were fortunate enough to do. Most of the old walls of the hall have been retained.

The site is admirably adapted for a public building of this kind, entrances and exits being obtained at the four corners of the building leading directly into streets, and the level of Trenchard Street being so much higher than Colston Street admits of easy and safe exit from the gallery and grand tier at that side of the building. The principal entrance to the building is from Colston Street under the existing loggia, from which a new vestibule having three large double doors leads to the entrance hall, on one side of which is a room for the directors, and on the other a reception room for distinguished guests. On either side of the hall, doors also lead to cloak-rooms for ladies and gentlemen, with a large crush-room between, and having communication with these rooms and the entrance hall. Two large flights of steps, each divided by a centre rail, lead to the principal floor. This has a corridor formed by a panelled screen round the entire hall, allowing the public to reach their seats without crossing the body of the hall. The floor is constructed in a manner suitable for dancing. Two large emergency exits are provided to Trenchard Street, which at these points is a few feet above the floor.

The principal approach to the grand tier is from the main staircase. This arrangement was adopted so that on certain occasions, such as a ball, direct access can be obtained from the principal floor to the grand tier, which on such occasions would be used as a supper-room. The risers of this floor are so arranged as to be capable of forming a perfectly level floor. Along one side of the tier, and overlooking the grand staircase, is a spacious balcony, which forms an ante-room to this part of the building. As in other parts of the hall, the columns are placed in such a position as in no way to obstruct the view of the audience. The gallery, which, like the grand tier, occupies three sides of the hall, has an open corridor the entire length of seating. This is so arranged that a view of the platform can be obtained from any part of it. There will thus be no danger of the public obstructing the passage to exits. Separate entrances to the gallery have been arranged for.

Particular attention has been paid to the arrangement of the orchestra. The seating is so arranged that the eye of each singer looks towards the conductor without turning the head, and the rise of seats is in the form of a parabolic curve, and of such a height that the mouth of one singer is above the head of the singer below. Each group of singers has a separate retiring room at the side of the platform at which they sing, they also enter as near as possible at the level they occupy. Thus the band enters at the lowest level of the platform, the soprano and alto by vomitoria at an intermediate level, and the tenor and bass at the highest point. The principal artistes have separate rooms as nearly as possible on the level of the platform, the few steps necessary owing to existing levels being placed in corridors at some distance from the actual entrance to the platform. Two spacious staircases are provided at the back of the orchestra; the sopranos and tenors entering from Trenchard Street, and the altos and bass from Colston Street. The band and chorus are exceptionally well provided for in having for their sole use two large refreshment rooms under the platform. The conductor and organist have each a spacious retiring room. A portion of the platform is made movable so that a large stage may be formed, the movable portion being removed to the basement by means of a large lift.

A magnificent organ, the gift of Sir W. H. Wills, and built by Messrs. Willis and Sons, London, occupies a space at the end of the hall. The chamber is about 22ft. square, and the height from engine-room to top of case is a little over 70ft.; it is blown by three electro motors. The ceiling over the organ was carefully designed to throw the sound of the organ into every part of the large building. Every attention has been paid to the acoustic properties of the hall. The grand staircase separating the two halls has been somewhat modified. The landings have also been considerably altered and a *foyer* at the north end, having large arched openings overlooking the staircase, has been added.

Serveries and lifts are provided in positions leading directly from the large kitchens in the basement to the principal floor, grand tier and chorus refreshment rooms. The kitchens will eventually be fitted up in the latest manner, and part of the scheme has already been carried out. The interior of the new hall has been treated in a broad manner. The decoration is concentrated on the ceiling and gallery fronts, the latter having ships and dolphins worked in the design, suggested by the legend of Colston. Small panels in the grand tier will be filled in with the names of celebrated composers and prominent citizens of Bristol. No attempt has been made to colour the hall at present, but a colour scheme is in the possession of the directors. The hall is capable of containing some 4,000 persons, being 1,500 more than the original building. Between 1,400 and 1,500 can be accommodated on the ground floor, 700 in the grand tier, and 1,000 in the gallery. Double windows have been provided, thus securing freedom from street noises. The building throughout is lighted by electricity, the fittings being effectively arranged. The staircases and landings have in addition gas jets, for use in case of emergency. The heating is on the low pressure hot water system, and the ventilation by means of fresh air inlets and large extraction fans. Fire appliances have been placed in convenient positions throughout the building. The work has been carried out by Mr. A. J. Beavan, contractor, Bedminster, and the company were fortunate in securing the services of Mr. John Perrott as clerk of works. The sanitary appliances are the work of Mr. A. S. Scull, of Redcliff Street.

CARPENTERS' COMPANY'S EXAMINATION.

SANITARY BUILDING CONSTRUCTION.

THE Carpenters' Company held its annual examination in sanitary building construction the week before last. The examination was that for which the lectures, delivered lately, lead up to. The average attendance at the lectures was over 74. The numbers entering for the examination this year were not so large as during the last few years, but the high average of merit was fully maintained: the actual average of the marks obtained being greater than last year. The board of examiners included Professors T. Roger Smith and H. E. Robinson, Mr. John Slater, B.A., V.P., R.I.B.A., Mr. W. H. Seth Smith, President Architectural Association, Mr. Wynter Blyth, M.O.H., Marylebone, and other well-known men. We give below the list of successful candidates arranged in order of merit:—Messrs. W. H. Johnson and John Sanderson, gold medals; Messrs. C. B. Burnett and Hugh Byron, silver medals; Messrs. F. C. Brown, W. J. Collins, J. S. Knight and J. I. Lonnen, bronze medals. Messrs. J. W. Devonshire, E. W. F. Martin, J. Rees and A. W. Stiles, Robert. Phillips, W. T. Sweett, Allan Storey, W. H. Gale and A. J. Griffiths. Candidates who sat to improve their positions but who failed to do so do not appear in this list.

A Presbyterian Church at Reading is to be erected in Caversham Road.

Engineering Notes.

A new Electric Lighting Works at Beckenham was formally declared open on Thursday last. The works have cost £37,000.

Important London Gas Scheme.—The South Metropolitan Gas Company gives notice that in the coming session of Parliament it will promote a Bill to enable it to purchase the property and rights of the Gas Light and Coke Company south of the Thames. The Gas Light and Coke Company now charges 2s. 10d. per 1,000ft. on the south side, the same as the South Metropolitan Company, and says it loses by it, and recoups itself by what it makes out of those on the north side, who pay it 3s. 5d. per 1,000ft.

London Bridge Widening.—Among the Parliamentary Bills for the next session is one by the Corporation of London for power to remove the walls, parapets, and carry out such work as necessary to enable London Bridge to be widened on both sides from Adelaide Place on the City side to the steps on the Southwark side by the inclusion of the present footpaths into the roadway. New footpaths will be constructed on either side of the present structure, supported on granite corbelling (see p. 341). Sir Benjamin Baker recommends a scheme for the expansion of the structure from 53ft. 5in., its present width between the parapets, to not less than 65ft. This will give a width of 34ft. 6in. for four lines of vehicles, 2ft. 6in. for central lighting, and 14ft. for each footway, instead of 9ft. 6in. as at present.

Bournemouth Tramways Scheme.—A Board of Trade enquiry was recently held at Bournemouth into the application of the Corporation for sanction to borrow £174,750 for the construction and electrical equipment of a tramway. The Town Clerk pointed out that the Poole and District Electric Traction Company had a light railway order to construct a tramway from Bournemouth to Poole, which was now being laid, and the Christchurch and Bournemouth Company had powers, in their order of last session, to construct a tramway between the two towns. They had running powers over the Bournemouth East line from east to west. Mr. Francis said, on behalf of certain property owners, that he did not object to the expenditure of £170,000 for the tramways, but to the item of about £5,000 for a generating station in Southcote Road, as it would depreciate the value of other property in that neighbourhood. Mr. Turrill also objected, but Mr. Lacey said the proposed site was the only suitable vacant one in the whole of Bournemouth. The Town Clerk said that if the Corporation did not complete the proposed works within two years from August last the other companies would have the power to step in and construct the line. As soon as the Corporation got the necessary sanction they would at once proceed with the work. The Inspector then concluded the enquiry.

Proposed Bridge over the Tyne at Shields.—A scheme has recently been adopted by private enterprise for erecting over the Tyne, between North and South Shields, a bridge of the "transbordeur" class, described and illustrated in our issue for January 10th last. The company, or syndicate, has been floated with a capital of £130,000, and the corporations of Tynemouth and South Shields are so far disposed to give every possible countenance and aid to facilitate the accomplishment of the undertaking, which will revolutionise the means of transit between the twin boroughs. The scheme has been so far advanced that the syndicate will be in a position to apply in the next session of Parliament for the powers they require. Mr. G. H. Gadsby, consulting engineer, Victoria Street, Westminster, and M. Arnoden, a celebrated French engineer, are the engineers who will carry out the scheme. The bridge will have a clear span of 640ft., and will be on the principle of a platform suspended by cables, which will be sufficiently large to accommodate tramcars, horses and carts, and 200 passengers, the whole to be worked by electricity. A five minutes' service will be established, and the electric power will be purchased from the respective corporations. Two piers will be erected at either extremity of the bridge.

QUANTITY SURVEYING.*

METHODS PRACTISED IN SCOTLAND.

By C. B. COWNIE.

WHEN I started to write this paper I intended to deal more fully than I have now done with the subject of quantity surveying itself, namely, the measuring of quantities and the mode of setting these down in schedule form; but on second thoughts I came to the conclusion that in a paper of this sort, a long list describing how the different materials in a building are measured would prove tedious and uninstructive, and that if dealt with generally the subject would be of much greater interest.

An attempt to deal with quantity surveying in any detail within the short space of an hour would lead to little instruction and much confusion in the minds of any but those who had a thorough grasp of the subject beforehand. I have therefore attempted to give the main principles of measuring without going into any unnecessary details.

The Object of the Schedule of Measurement.

The business of a quantity surveyor is to ascertain the amount of work done in the construction of a building and to adjust the value according to a determined basis. A schedule of measurement constitutes this basis, and is drawn up to help the contractor when estimating to arrive at the amount which the work will cost him by supplying him with the quantities of the different materials and the different varieties of labour required in the construction of the building. At the same time the schedule affords the different contractors a uniform basis for competition. The items of a schedule describe the work in more or less detail, according to its nature. In some cases one item deals only with the material, and another only with the labour, and in other cases both labour and material are included in one item. It is found that no advantage is gained by measuring certain classes of work in much detail and a convenient base to work upon is therefore discovered and used in practice, *e.g.*, instead of measuring a door in detail by stating separately the stiles, rails, panel mouldings, &c., it is usual to describe the different parts and state at the superficial foot. The prices for the different items the contractor can, in most cases, only learn by experience. To the prime cost of materials such as stone or timber he requires to calculate and add the cost of carriage, and in most cases of labour also. Even in estimating from a schedule of measurement there is a certain amount of speculation. The contractor takes the risk of finding, when executing the work, that through some error in judgment his rates are too low to give a reasonable profit, but by means of the schedule of measurement this risk in contracting is perhaps reduced to a minimum. Of course, the schedule of measurement serves another purpose by giving the architect a basis to work upon. With the contractor's rates before him, the cost of any deviation from the plans can be calculated with ease, whereas without fixed rates he would have no hold upon the contractor should he render an exorbitant account for the work resulting from such deviation.

Jobbing Work.

There is, of course, certain work in the erection of buildings, and more especially in the alteration of existing buildings, which cannot be satisfactorily measured or dealt with in a schedule of measurement. Such work is usually charged as time and material and priced at the current jobbing rates. The jobbing rates are compiled by the trades' associations and issued from time to time as the wages or prices of material rise or fall. These rates are, however, for ordinary jobbing work in connection with a contract, much higher than is compatible with a reasonable profit, and it is therefore usual for the contractor when estimating to agree to discount a percentage on these rates for all jobbing work connected with his contract. The checking of the time and material charged by the contractor in his jobbing account is usually done by the clerk of works. Every district has its own mode of measurement and its own trade allowances. In some parts of the country, to avoid disputes, these have been considered by committees of the local surveyors and builders and formed into sets of rules and regulations, issued in printed form. In Edinburgh the modes of measurement for only two trades—namely, mason and brickwork and carpenter and joiner work—have as yet been published, but steps are now being taken to compile sets of rules for the measuring of the other trades as well. Meanwhile there are certain unwritten rules and customs for the measuring of these trades which are generally adhered to. The tendency at the present time in measuring is to go more into detail. The measuring of work too much in detail is not unattended with evils, one of which is that with inexperienced contractors the increase in the number of items is almost sure to produce a corresponding increase in the amount of the tender.

The Schedule of Forty Years Ago.

It is interesting to look back forty or fifty years and compare the number of items in the schedules of that time with the number of those of the present day. Then it was only with very large jobs that a mason's schedule exceeded three or four pages. The measurer in those days roughly allowed for any extra labour the contractor might be put to in executing certain work by adding extra measurement. For example, instead of stating circular rubble or arching in separate items he would give double measurement and include the whole in the quantity as ordinary rubble. The quantities of rubble work being arrived at in this way the whole would be reduced either to 12in. or 24in. thick, and stated at per rood of 36 sq. yds. in one item.

The whole of the hewn work of rybats, sills, lintels, corners, and even the outside face of the building, if necessary, would be slumped together in the same way, and stated in one item at per cube foot. In carpenter and joiner work the same principle of slumping was practised. The wood in bound roof trusses was taken by the cube foot; the contents of wall plates were added to the superficial measurement of the roofing; door standards of all sizes were reduced to 3in. square and measured by the lineal foot; facings, skirtings, door stops, &c., less than 8in. wide were reduced to 4in. wide and taken lineally, and all those more than 8in. wide were taken as plain lining in a superficial quantity. One can easily understand that only a small number of items would be necessary in two schedules drawn up on this plan. This mode of measuring meant practically fixing certain rates, or at least their proportions, for the contractor, as it was pure conjecture on the part of the measurer to assume, for instance, that sunk hewn work would cost double as much as plain, or that circular hewn work would cost three times as much as plain.

A schedule made up in this way was of little practical use either to the architect or to the builder, as it was utterly impossible for anyone but the measurer to unravel its mysteries; and even he, without his notes of measurement, would be able to make little of it. The cost of the work would, moreover, be apt to depend as much upon the measurer as upon the contractor, on account of the uncertainty and indefiniteness of the mode of measurement.

Mason Work.

In giving a sketch of the mode of measurement at present in vogue in Edinburgh, I propose to follow the order of an ordinary schedule.

The first heading in a schedule of mason work is usually "Excavations and Foundations." Stripping of the surface soil is the first thing required in the preparation of a new site for a building. The depth of this soil is usually about 12in., but varies according to the agricultural richness of the ground. Should farther excavation be required it is measured by the superficial yard if it be more than 12in. deep, and by the cubic yard if less than that depth.

In measuring surface excavation over an uneven piece of ground, vertical sections would be taken at intervals, and the areas of each section calculated. From an average area of two of these sections the excavation in the portion of ground lying between them could then be calculated.

If the excavation be in rock an extra price is given over ordinary excavation for rock-cutting. Excavations for foundations are measured the nett size if the foundations are of concrete, but if they be of stone an allowance of 3in. is made at each side of the foundation to give room for setting, and a further allowance of 3in. for every foot of depth is given for the batter of the earth. Excavations from different depths are kept separate, and the cost of all shoring or strutting required at trenches, &c., is included in the prices of excavation. The foundations themselves, whether of stone or concrete, are taken in superficial or cubic quantities, according to their thicknesses.

Passing on to rubble, the whole of the stonework from the top of the foundation courses is measured as rubble, except steps, plats, hearths and pavement. All cube stone in piers and in dressings is included in this quantity to go for building. Rubble more than 2ft. thick is reduced to that thickness, and rubble less than 2ft. thick is stated in different items according to its thickness. All rubble is measured nett except in the case of circle walls, which are girthed. The projections of sleeper scarcements, pilasters, cornices, string courses, &c., are measured the nett size and reduced to the thickness of the respective walls to which they belong. In taking a balustrade for rubble, properly speaking, the rubble in each baluster should be measured nett, but in practice the balustrade is sometimes measured as if it were solid, and stated in an item by itself. The daylight sizes of all openings are deducted from the rubble. In the case of windows the rubble in the breasts is usually thinner than in the main wall, but this is measured at the full thickness to allow for the scuntions required at the angles.

Beamfilling at wall heads between the rafters, whether of rubble or brick, is not included in the quantity of rubble or brick, as the case may be, but is stated separately according to its height, and measured by the lineal yard. This rule is necessary on account of the extra labour required in packing the rubble in this position after the roof is on. Scribbled scuntions are required at all angles inside the building and below the ground line outside the building, and are measured by the lineal foot. Scuntions are also required behind the rybats at doors and windows, and if the inband rybats pass through the wall and break bond with the scuntions then half the height only is required. Stones built into walls to form beam rests are numbered, and savings over wood safe-lintels of long stones or brick arches are either numbered or measured by the superficial foot of safe lintel-covered. The mason takes delivery of and raises and sets the iron and steel work. The lengths and weights of the beams, &c., are usually given, and the light beams kept separate from the heavier ones. An item is sometimes given in the mason's schedule for hoisting and setting the joisting and roofing timbers for the joiner; this is an item which saves the joiner a considerable amount of trouble and costs the mason comparatively little expense, as he has his steam crane or other appliances already upon the site.

Regarding the measurement of brickwork there is not much to be said. The walls are sometimes stated as so many bricks thick, or each brick is calculated as 5in. on bed, to allow for the thickness of the joints, and the walls stated as 15in, 20in. or 25in. thick, as the case may be. In practice the walls turn out rather less than these thicknesses. The sizes of the bricks themselves vary considerably according to their make, and it is impossible to tell to an inch or two the actual thicknesses of a brick wall. The plumbings at all external are measured in brickwork, except in the case of 4½in. partitions, which are girthed. The plumbings at internal angles, however, are included in the price of the brick, and are not stated separately. Enamelled or other face bricks are measured as extra price over ordinary brickwork. All stonework, such as lintels, sills or ashlar, if built into a brick wall, is included in the brickwork to go for building, and is not, of course, measured again as rubble. Voids in

* Paper read before the Edinburgh Architectural Society on November 21st, 1900.

brickwork are deducted the daylight size, as in rubble, but the thinner brick in window breasts is deducted and stated in a different item according to its thickness. Bevelled plumbings and angles rounded for plaster are measured by the lineal foot. Brick arches are measured in the superficial quantity of brickwork and an extra price is given for forming the arches according to their size, and also for forming springers.

Measuring Hewn Work.

We now pass on to the consideration of the measuring of hewn work and cube stone, which is perhaps the most interesting part of quantity surveying. Stonework may be measured by the lineal, superficial, or cubic foot, as the case may be, or each stone may be stated separately with its description. Sills, lintels, base courses, plinths, cornices and the like, if of small section, are measured by the lineal foot, the sizes, girths, and descriptions of hewn work being stated. The limit sectional size of stone to be measured in this manner is 12in. by 12in., according to the rules. For instance, a sill or lintel 12in. by 12in. could be measured lineally and the price would include the hewn work, but one 12in. by 13in. would be measured by the cube foot and the hewn work taken by the superficial foot and stated separately. This rule is, however, not always strictly adhered to with sections slightly above 12in. by 12in., partly on account of the extra trouble which the second method entails. Corners, rybats, upstarts and mullions are measured by the lineal foot for labour and material. In measuring the hewn work on ordinary lintels and rybats the girth is taken to the inside angle of the check, beyond that point being taken as scribbled work.

Solid stonework in piers, &c., whether built in courses or otherwise, is measured by the cube foot. Stone in the larger sills, string-courses, cornices, &c., if less than 12in. thick, is measured by the superficial foot and if of more than that thickness by the cube foot. The stones are classified according to their sizes as below 5ft. cube, or from 5ft. to 10ft. cube, 10ft. to 15ft. cube, and so on, progressing each time by 5ft. This of course is necessary as the quarry prices of the stone vary according to the sizes of the blocks.

If a stone, when wrought, is of an irregular shape, the smallest possible rectangular size from which it could be cut is taken for the cube stone. In measuring the cube of a rectangular stone the exact finished size is taken and not the original size of the block before dressing. This is a general rule all over the country, except, perhaps, in Manchester, where 1in. each way beyond the nett dimensions of the stone (except in the case of ashlar), is allowed for the waste in dressing. The hewn work of stones where exposed to sight is measured by the superficial foot and described as polished, scabbled, droved, or scribbled, &c., and also as plain, sunk, double-sunk, splayed, circular, moulded, sunk-moulded, circular-moulded, circular-on-the-circle, entasised, or otherwise. Polished, scabbled, and droved work are different varieties of hewn work put on stones where exposed to sight.

Scribbled work is taken for the stonework which will be covered up by plaster or otherwise and will not be exposed to sight. Plain hewn work is the even surface worked on a stone without sinking more than necessary to remove its irregularities. Sunk hewn work is measured on stone where the mason has to sink a portion of the surface from one level to another, as in rebates, &c. Double-sunk work is measured where this sinking is repeated. Moulded work if under 12in. girth is measured by the lineal foot, and if above that by the superficial foot. The extreme lengths of moulded work at internal and external angles are measured. Sunk-moulded work is taken at all places where the mason cannot work in a straight line from his zinc moulds. The moulded work on a stone forming an internal mitre of a cornice would, for instance, be sunk. All dentil, egg and dart, or other ornaments are measured by the lineal foot as extra price over moulded work. Arches, if under 12in. by 12in., are measured by the lineal foot for stone and labour; if above that size, by taking the cube stone in one item and the hewn work in another. Circular hewn work is the labour required to form convex surfaces, as on the shafts of columns. Sunk-circular hewn work is the labour required to form concave surfaces, as for the soffits of arch stones, or it may be ordinary circular work worked on a sunk face. Circled-circular hewn work is that required to form a sphere or the soffit of a niche. On account of the varieties of circular hewn work it is better to state always what the work is to form. All plain beds and joints are included in the price of the stone, except in the case of arches. The sunk, splayed, circular, and radiating joints are measured separately for extra price over ordinary joints. In the case of arches, however, the radiated and arched joints and beds are included in the price of the stone.

This mode of including the labour of working the beds and joints in the price of the stone is not general over the country. In some parts of England the custom is to measure the whole of the beds and joints, and in other parts to measure only one bed and one joint to each stone. There is not a great deal of advantage in going to the trouble of measuring beds and joints, as every stone requires them, and the builder can after a little experience very easily calculate the price of such, and add it to the cost of the cube stone.

The facework of walls is described according to its quality and measured by the superficial yard. All openings are deducted, also all the stone dressings such as rybats, sills, lintels, panel stones, &c. An allowance of 3in. is made for bond on both walls at internal angles, and at upstart rybats and such like. The extra labour and waste cutting and fitting facework to the bevel or circle is measured by the lineal foot.

Raking out the joints and pointing with lime or cement is measured by the superficial yard, stating whether this has to be done while the work is in progress or after the roof is on. In the latter case the cost is considerably greater, as the erection of special scaffolding is necessary after the building is completed.

The stone in plats and landings is measured by the superficial foot, the wall-holds and cover included. Plain, moulded, and piend-checked edges are measured by the lineal foot.

Digging and refilling tracks for drain pipes are measured by the lineal yard and classified according to their depths. The price includes any planking or shoring required. Fireclay drains should be according to the mode, measured by the lineal yard the nett finished length over all bends, branches, &c. A better way, however, is to allow 3ft. for each length used, as the contractor has, in many cases, a great deal of waste in cuttings. The only disadvantage which this method has is, that once the drains have been covered up the surveyor has no means of checking the number of pipes actually used. General items are given for tools, tackling, sheds, watching, lighting, and jobbing for other tradesmen. In Edinburgh the usual practice is for the mason and painter to provide their own scaffolding, and for the joiner to provide scaffolding for all the rest of the trades. These other tradesmen erect and shift the scaffolding to suit themselves. Each contractor carries out the rubbish arising from his own department, and the whole is carted away by the mason. Either the mason or the plumber lays on the water, but the former pays the rates for water required for his department, and these amount to about ½ per cent. on the total cost of the work.

Carpenter and Joiner Work.

The rules for measuring carpenter and joiner work in Edinburgh were only issued about a year and a half ago, and were drawn up by a committee of surveyors and joiners a short time before the formation of the Ordained Surveyors' Society. The new mode altered the existing methods considerably, and entailed extra trouble to the surveyor by going more into detail and increasing the number of items in a schedule. One difference in the modes is in the measurement of joisting, which is now taken by the cubic foot instead of by the superficial yard as formerly; and another difference is in the numbering of all mitres, and scribings of skirtings, architraves, facings, &c., which is required in the new mode, but which in the old mode was included in the price per lineal foot. In measuring safe-lintels over voids, behind stone lintels, the old plan was to allow one inch for every foot of span for the thickness, to add 9in. on each side for wall-hold, and to state at the cubic foot. In most cases this allowance of one inch to the foot of span was more than necessary, and the contractor knowing this, put in a price which would only cover the cost of what was actually required. By the new mode, safe-lintels are measured by the superficial foot and the actual thicknesses stated. Centres for arches are described and numbered, the price, including the slack, blocks, and the taking down again when required. Wall plates are measured by the lineal foot, the laps being included. Special bat bolts for fixing to the wall head are numbered. Sleeper joisting, joisting for upper floors, bridles, trimmers, &c., are now measured by the lineal foot. Formerly joisting was stated at the superficial yard, the distance apart being given. By this way the quantity of sleeper joisting was the same as that of the flooring. The objection to this mode was, that by taking the nett floor area one of the joists against the wall was not included in the measurement, and the contractor was thus unable to ascertain the exact number of lineal feet of joisting from the superficial quantity given. In the case of rafters, branders, &c., which are still measured by the superficial yard, this inaccuracy is rectified by multiplying the length of the slip-joist or brander, as the case may be, by the distance between the centres of the timbers, and adding the quantity to the superficial measurement. Dwangs in joisting, whether solid or herringbone, are taken by the lineal foot over the joisting. In a framed roof-truss the timbers are described with method of jointing and measured by the lineal foot. Iron straps or bolts fixing the timbers are numbered. In ordinary roofs the timbers, such as rafters, ties, struts, platform joists, &c., are measured by the superficial yard, the extra or slip timbers in each section being included as described above. In making deductions for chimneys, cupolas, &c., from timbers measured in this way, the nett size of the opening is not deducted, but an extra or slip timber is allowed for in the measurement.

The labour and waste in cutting and fitting rafters at piends and flanks is stated at the lineal foot, both sides being measured. Flank and piend rafters and flank plates are measured by the lineal foot. Declivity or tapered pieces laid on the top of the joisting to form a run for the water off a platform roof are measured by the superficial yard in the same way as rafters are. Framing and astragals of cupolas also, closed curbs, facings, &c., are measured by the lineal foot. Strapping, brandering, ceiling joists, &c., are dealt with in the same way as rafters. Standard partitions are measured by the superficial yard, the runners and dwangs being taken by the lineal foot. Lath is measured by the superficial yard, the cuttings and waste to the angle or circle being allowed for in the measurement. Steps and stairs are described and numbered, the price, including the tread and riser, and all glued blocking, stringers, moulded plates, skirtings, handrails, &c, are measured by the lineal foot. Scrolls, ramps, mitres, &c., of the handrail are numbered. Grooved and tongued linings on walls, &c., are measured by the superficial yard. Bound linings are, however, measured by the superficial foot. Coping at top of lining, picture and cornice mouldings, skirtings and base plates are all measured by the lineal foot, the mitres, scribes, bolts, returned ends, &c., being numbered. Sash and case windows are stated by the superficial foot, and the price includes pulley boxes, pulleys, cords or chains, weights, and case. An allowance of 9in. in the width and 3in. in the height is made over the daylight size of the mason work; the daylight size in the case of mullioned or transomed windows being understood to be the distances between sill and lintel and rybat and rybat. Mullion or transome plates if panelled or moulded are measured by the lineal foot for extra price over the superficial measurement. Casement windows are

measured by the superficial foot, but the price is for the sash only, and does not include the sill and frame, as in the case of sash and case windows, these being measured by the lineal foot in detail. Architraves or facings are measured to the floor and the blocks are numbered for extra price. The mitres of these are also numbered. Joinery finishings and fittings are usually measured in detail. The mitres, butts, scribings, &c., of mouldings, leaseplates, and such-like are numbered. Allowances are made by the joiner contractor for jobbings for other tradesmen, and for dooks, straps, &c. In some cases the joiner cuts holes for the dooks, bars, &c., or the mason may do this for him. Allowances are also given for masons' sheds, scaffolding, tools, housing the moulds for the plasterer, and for watching, lighting, &c., if this is not done by the mason.

Doors are measured by the superficial foot and their finishings by the linear foot. Ironmongery is usually included in the joiner's schedule. The different articles are usually numbered. Ordinary butt or backflap hinges are known by their vertical heights, and tail hinges by the length of the arm from the knuckle. Rim, mortise, and press locks are known by the horizontal length and padlocks by the horizontal width when the lock hangs perpendicularly. Barrel and tower bolts are known by the length of the barrel itself. Lock furniture or mounting may be stated by the set or by the number of sides of doors provided.

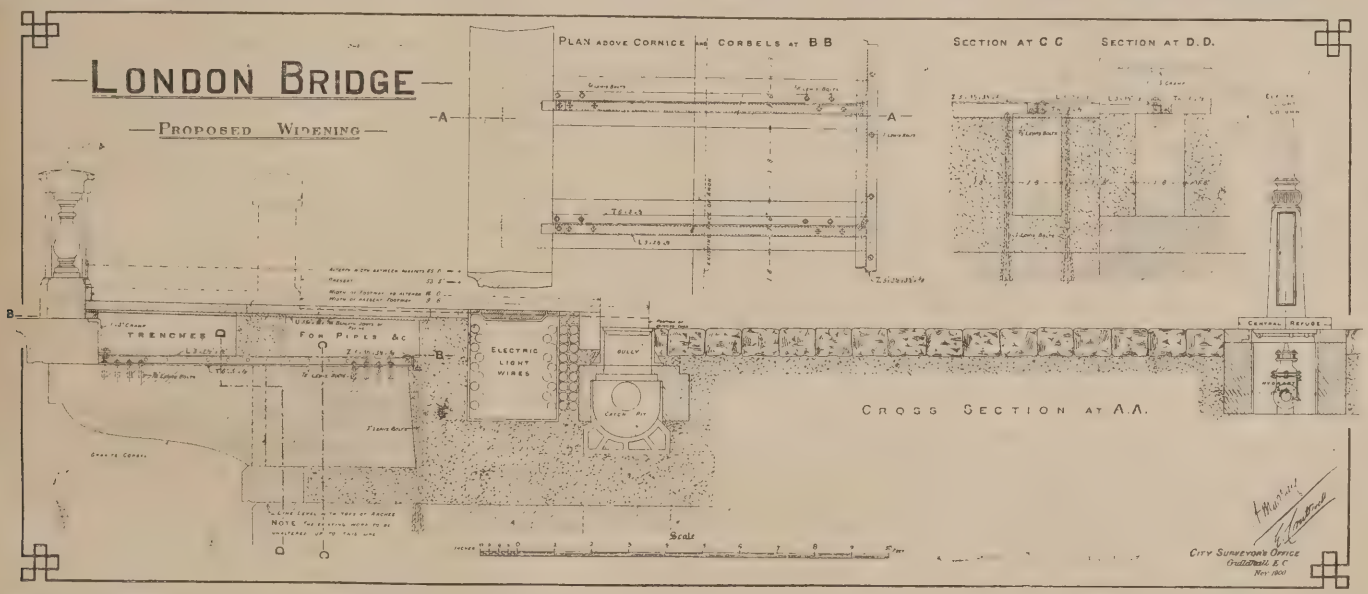
Glazier Work.

Glass is measured by the superficial foot. The glass in most cases is measured over the astragals, whether these be straight or circled, and the contractor's price covers the labour in cutting and the waste. As the price of plate glass depends very much upon the sizes of the panes, the panes which vary more than two superficial feet are stated separately. Bevelling edges of plate glass is taken by the lineal foot, according to the breadth of the bevel.

Plumber Work.

There are no recognised rules for measuring certain items in plumber work. It is therefore usual to state in the schedule the way these items are taken. Head in flashings, &c. is measured by the lineal or superficial foot according to its breadth. The weight of the lead for ordinary purposes is 5lbs. or 6lbs. per superficial foot. The lighter lead is used for flanks, aprons and flashing lights, &c., and the heavier for platforms, gutters and ridges and piends. For very cheap work 4½lb. lead is used in place of 5lb., and for superior work 7lb. lead may be used in place of 6lb. The laps in lead work are included in the measurement. Zinc for roofing is manufactured in sheets of two sizes, 7ft. by 3ft. and 8ft. by 3ft. Almost all the zinc used here is manufactured by the Vieille Montaigne Zinc Mining Company. The zinc is made in nine different weights, which are distinguished by the company's own gauge. For platforms Nos. 14, 15 or 16 gauge may be used and for flats or piends Nos. 13, 14 or 15 gauge. In this case the higher the gauge the thicker is the metal. This is different from the Birmingham wire gauge in which the thicker the metal the lower is the number of the gauge. Zinc on platforms and roofs is measured by the sheets and half-sheets—i.e., if anything less than half a sheet is required for a particular portion of the roof, then a whole half-sheet is allowed in the measurement. Likewise if anything over half a sheet and below a full sheet be required, then a whole sheet is allowed. The reason for measuring zinc in this way is that the cuttings off the sheets are of little use to the plumber, as they cannot, of course, be melted down, as is done with lead cuttings, and be used for other purposes. In the case of covering dormer haffits and such like with zinc, it is better to measure the nett amount used, as is done with lead, as the pieces of zinc are often of triangular shape, and two haffits can in that case be sometimes covered with the one sheet cut in two pieces. Zinc roll caps to cover the joints of the sheets are measured by the lineal foot, and the slip, kneed or mitred and nozzle ends numbered. Rhones are usually measured the nett length of extremes, the angle pieces, stop ends, and drop pieces being numbered for extra price. Conductors and other cast-iron pipes are measured in 3ft. and 6ft. lengths. This is, I think, the usual practice in Edinburgh, but there is no reason why rhones which are cast in 3ft. and 6ft. lengths should be measured nett, and the cast-iron conductors in 3ft. and 6ft. lengths, unless it be for convenience to the measurer, who can more easily count from below the number of lengths and half-lengths of the cast-iron pipes than measure the exact length with a tape. The prices of rhones and pipes include the jointing and fixing in position with ordinary holdfasts. Holderbats, ornamental ears, and other special fixtures for cast-iron pipes are numbered for extra price over ordinary holdfasts. Cast-iron rain conductors and waste pipes are usually jointed with hemp and red lead if outside the building. Cast-iron soil and all waste pipes inside are jointed with hemp and molten lead run in and staved. Lead water pipes are stated according to their weights specified by the Water Trust. Pipes supplied from the main require to be heavier than those supplied from the cistern. Lead pipes up to 1¼in. bore are specified as weighing so many lbs. per yard. But lead, waste, or soil pipes are specified according to the weight per superficial foot of the lead from which they are made. The joining of the supply pipes to the main in the street is done by the water company, but the fee of 5s. is paid through the plumber. Gas meters are supplied by the Gas Commissioners, and in towns the pipe between the main in the street and the meter in the building is provided and laid by the company. Allowances for wrapping exposed water pipes in felt and for upholding the plumber work for a certain term, usually two years, are given.

Plaster Work



is measured by the superficial yard. The height of plaster on the walls of a room is taken from floor to ceiling over the baseplate or skirting. Some surveyors give an extra price over the plaster for the pugging behind the baseplate or skirting, but the usual practice is to let the extra measurement of plaster go for the pugging. Deductions at doors, fireplaces, &c., are measured nett daylight size. If the cornices be small and have no brackets the plaster is measured behind these.

In patching old work considerable labour is required to make a proper fixing between the old and new plaster by softening the old work, and for this an allowance of 1ft. is usually given. In very small patches this allowance is too much and it is better to make nett measurements and state them in a separate item. Plaster beads, arrises, splays, mouldings, cornices, &c., are measured by the lineal foot at extreme points and their mitres and butts numbered. In cornices where four mitres are necessary in every room, the price per lineal foot is sometimes held to cover these and the extra mitres only are allowed for. A better way is, however, to number the whole of the mitres. Mitres or butts may be either numbered, or allowed for by adding 1ft. for each mitre, or 6in. for each butt to the lineal quantity of cornice. Iron and steel work is usually priced at per cwt., but the lengths of beams, angles, tees, &c., should also be given. Angle-plates, bolts and holes drilled in the beams, &c., are described and numbered. The cost of wood patterns required for cast-iron work are usually included in the price per cwt., but it is important to state this explicitly in the schedule, as, if this be not done, the contractor is not slow to claim the patterns as an extra. In iron or steel roofs, where the amount of labour in fitting and fixing is sometimes as great as the cost of the material itself, the materials, such as angle, tee, or other steels, the bolts and rivets and the labour in drilling holes and cutting and fitting, should be minutely described.

The weights of wrought iron and steel are usually calculated with the help of the handbooks of the different makers, and the weight of cast iron can be ascertained by calculating the number of cubic inches in the casting and multiplying the result by 26, which gives the weight in pounds. The prices of iron and steel work include carriage and delivery at the building.

Glasgow Mode.

Having taken note of the principal points in the Edinburgh mode of measurement, it might be of interest to glance very briefly at the more prominent features of other modes. The Glasgow mode for mason work differs from the Edinburgh mode practically in only one respect, which is that cube columns, pillars, cornices or other courses which go through the full thickness of the wall are not measured as rubble, as is done in Edinburgh, but the price of the stone itself includes the building and setting.

The Glasgow mode for carpenter and joiner work is very similar to the Edinburgh mode. One difference, however, is in the measurement of all the roof timbers, such as rafters, by the neal foot instead of by the superficial yard as is done here. The plaster, slater and painter trades are measured in Glasgow in much the the same way as in Edinburgh. The modes for plumber work, however, vary considerably, the great difference being that lead and zinc are measured and calculated to bring out the nett weight, and are charged per cwt., while the Edinburgh practice is to state these by the superficial foot. The English modes of measurement vary, not a little, from those employed in Scotland and also from each other, for almost every country has a different mode. Rubble walls are measured by the cube yard and the stone in cube piers, &c., is not included in the quantity. The price of cube stone does not include the working of plain beds and joints, but these are measured by the superficial foot. In some districts the whole of these beds and joints are measured, and in other districts only one bed and one joint are taken for each stone. In carpenter work, as a general rule, all timbers above 3in. square, such as joisting, wall plates, rafters, purlins, ties, standards in partitions, &c, are taken by the cube foot. Lathing, flooring, and such like are taken by the square of 100ft. super. In Manchester two customs are practised which are peculiar to the district, one being that all brickwork of whatever thickness is reduced to 4½in. thick and stated at the superficial yard, and the other that an extra item in the carpenter work is given for superficial labour and nails in connection with flooring, roofing, &c.

In London the dimensions are abstracted and put into schedule form in rather a curious fashion. Instead of the schedule being divided up under different headings as is done here, the whole of the quantities in each trade are slumped together and set down as follows: First, the cubic quantities commencing with the highest denomination and the items of each according to their value; second, the superficial quantities; third, the lineal quantities, both arranged according to their denomination and value; and fourth, are stated those articles which are enumerated and these also according to their value.

In England it is usual to contract with one party for the execution of all the trades required to complete the building, the contracting party sub-letting such of the trades as he desires. It will be seen that much diversity exists in the modes of measurement practised throughout the country.

The establishment of a uniform mode of measurement for Great Britain is most desirable, but at the same time most difficult of accomplishment. Each part of the country is tied up with its local customs, and the mind of the average practical artificer is too conservative to accomodate itself to any new methods of calculating his labour. One of the objections to the present system is that contractors cannot readily offer for work outside their own district without running a certain risk in pricing a schedule measured according to a mode with which they are not acquainted.

In France the method of contracting is very different from the methods employed in this country. The plans are not measured before the building is erected, but two surveyors are employed to measure up the work as executed, at completion. In Paris the various tradesmen tender to execute the work at certain percentages below an official schedule of prices known as the "Série-de-la-Ville-de-Paris" (i.e. the List of Prices for the Town of Paris). The contractor who offers the largest discount on these prices is then accepted, and forthwith proceeds with the work. At completion he employs a surveyor, known as a "métreur," who measures up the work, and also prepares drawings of the building as executed. The surveyor's report, together with the drawings, is then forwarded to the architect, who thereupon appoints a second surveyor known in this case as a "verificateur" or auditor, who revises and checks the measurements on behalf of the proprietor. Throughout Europe quantities, either prepared from the plans or from the building itself after execution, form, as a general rule, the basis of contracting. In America the usual custom at present is for the contractor to make rough measurements himself from the plans and with the help of a specification supplied by the architect, and an offer is often made to execute the work for a slump sum. There seems to be, however, a strong feeling throughout the country in favour of adopting some such system as ours.

The Evolution of the Modern System.

I shall now say a few words upon the manner in which the practice of measuring has developed into the modern system. In the case of large buildings erected in the Middle Ages, such as cathedrals, abbeys, churches, or colleges, the custom was for the ruling authority to supply from its own property the stone, timber, &c., which it produced, and to purchase such other material as it did not produce. The labour, as far as the masonry was concerned, was executed from the twelfth to the fifteenth centuries by the Brotherhood of Freemasons, who were paid by time. The other tradesmen in connection with the building were also paid by time, the rates per day being often regulated by Act of Parliament. Occasionally an individual workman would be employed to supply items as a single door or window. This system, by which the proprietors provided the materials and employed tradesmen to perform the labour did not of course originate in the twelfth century, but can be traced back to the earliest times. In Egypt and other countries the labour would often be done by slaves. The custom of erecting a building and having it afterwards measured by a surveyor was practised about a century ago. The prices in some cases were arranged beforehand, and in other cases were not; or the prices of a few of the leading items only, such as the rate per rod of brickwork or the rate per cube foot of timber, would be arranged beforehand and the rest left to be settled by the measurer at completion, the tradesman appointing one surveyor and the architect or building owner another. The great expense of this system led to its gradual abandonment. The client did not know beforehand what the work would cost and the uncertainty as to the mode of measurement led to frequent disputes. In the erection of several buildings about sixty years ago a clerk of works was employed who purchased the materials and engaged and paid tradesmen to execute the labour.

The desire of the building owner to know the cost of the operations beforehand led to the system of contracts by which an offer to execute the whole of the works would be given by one master builder, who either prepared his own quantities or employed a surveyor to do this for him. Each contractor who tendered was put to so much expense by this system that the increase of competition led to an arrangement by which the builders met and appointed a surveyor to prepare the quantities, arranging beforehand, either that the expense should be mutually borne, or that the succesful contractor should pay the whole of the surveyor's fee. This arrangement has now been superseded by the present one, under which the surveyor is appointed by the architect and the fees paid by the proprietor. In England two surveyors are sometimes appointed, one by the architect and another by the contractor, in which case both surveyors are supposed to act together.

Liability.

In several towns in the colonies very accurate modes of measurement have been adopted. In Melbourne the proprietors and contractors are protected from suffering any loss through the carelessness or incompetency of the measurer, the latter being required, before starting business, to make a deposit of £500, from which sum any loss to the proprietor through over-measurement or loss to the contractor through under-measurement is made good. Of course, in this country, damages might be obtained from the measurer in a court of law if such a discrepancy in his final report were proved. A case of this sort, I believe, was brought up in the Court of Session some months ago, in which the measurer, who happened also to be the architect, was found liable to the proprietor for some hundreds of pounds which he had overpaid the contractor through overloaded quantities.

After the completion of a building it is usual for the measurer either to measure up the whole of the work as executed or to adjust the schedule measurements. In Government jobs, however, the contractor undertakes to execute the whole work for the amount of his estimate, and is held bound to complete his contract for this slump sum. Of course any alteration caused by a deviation from the original plans is adjusted, but any inaccuracy in the schedule, whether it be caused by over-measurement or by under-measurement or omission is not taken account of. This arrangement is, needless to say, thoroughly unsatisfactory to both parties and cannot be too strongly condemned. If the quantities happen to be overloaded, then the builder is receiving payment for work he has not done, while on the other hand, if the quantities of work be understated then the proprietor is receiving work for which he has not paid. This process is, nevertheless, practised not infrequently in some parts of the country. The schedules are issued and at the same time any responsibility of their accuracy is repudiated and the contractor is informed that he may if he wishes verify the quantities before tendering. This, of course, the contractor can only do with the greatest difficulty.

Impracticable plans and inaccurate specifications and schedules of measurement may be placed in the same category and if the conditions of contract stipulate that the plans and schedules are simply in the nature of information supplied to the contractor to facilitate his tendering to execute the work, then the contractor is bound to fulfil the contract. This practice of issuing plans and schedules under these conditions is not common in Scotland, but in England no small number of similar cases have been upheld in the courts of law. The system is only excusable in the case of very small contracts when the amount of the estimate required is too small to warrant the expense of the ordinary schedule and the adjustment at completion which it entails.

The most satisfactory way is undoubtedly to make the schedule of quantities the basis of the contract. There are, of course, objections even to this mode, one being that the proprietor does not know for certain before the work is commenced what the exact cost will be; there is, therefore, a chance of the proprietor being called upon to pay at the completion of the building a larger sum than he had anticipated when entering into the contract.

Extras upon a contract may occur in various ways, through deviations from the original plans, through omissions from the schedule of measurements, or through some unforeseen circumstances arising in connection with the site or the building. Extras can only be priced and paid for at schedule rates if the work is done while the contract is in progress. Work done after the contract is completed must be looked upon as a fresh transaction.

As a result of the keen competition in offering for work contractors are apt in some cases to quote unremunerative rates for certain articles and trust to their being able to obtain permission to replace these articles by others for which no schedule rate is given. As it is often impossible to get proportionate rates for these new articles, a considerable amount of extras may occur in this way.

The pricing of the contractor's work in the final report of the work as executed is done as far as possible by the surveyor, and those prices about which the surveyor and contractor differ are sometimes left to the decision of the architect, who acts as arbiter. In other cases the conditions of contract may stipulate that the surveyor will finally fix the rates.

Society of Ordained Surveyors.

Before closing, it might be of interest to say a few words on the new Society of Ordained Surveyors in Edinburgh. This society was formed last year with the objects—(1) of advancing the professiou of surveying; (2) of considering and discussing any subjects or questions connected with the profession

(3) of establishing and conducting examinations in connection with the qualification of candidates for admission to the society; and (4) of establishing a uniform mode of measuring all kinds of artificer's work. At the start the society admitted to its ranks all persons who had been ordained as surveyors prior to the first general meeting of the society. The examining board consists of a representative nominated by the magistrates and town council, a representative nominated by the Sheriff of the Lothians and Peebles and three members of the society elected annually. All applicants for admission to the society must have served a five years' apprenticeship with an ordained surveyor or a Fellow of the Institute of Measurers of Glasgow. An apprentice must pass a preliminary examination on general knowledge within twelve months of his admission to an office. All apprentices who have passed the preliminary examination and completed their terms of apprenticeship may present a petition to the magistrates and Town Council or to the Sheriff of the Lothians to be ordained and thereafter come forward for examination before the Examining Board of the Society. The examinations are held twice a year in the months of April and October. The preliminary examination occupies one day. The final examination occupies two days, and includes an oral examination. The subjects are quantity surveying, land surveying and levelling, and building construction, including the strength of materials. Candidates are also required to produce the notes of dimensions of a building they have measured, along with the plans from which the measurements were made. The examination fees for the preliminary examination are £1 1s., and for the final examination, £6 6s. After being found duly qualified by the Examining Board, the candidate must take the oath before the magistrates and Town Council, or before the sheriff, and is then qualified for admission to the society. After being proposed and seconded, he will in course of time be admitted, provided that he has paid the entrance fee of £4 4s. and first annual subscription of £2 2s.

The custom of ordaining surveyors through the magistrates and Town Council or the Sheriff of the Lothians is evidently a very old institution. I have endeavoured to trace its origin, but have so far been unsuccessful. Prior to the formation of the Society a surveyor might be ordained by applying either to the magistrates and Town Council or to the sheriff. If he applied to the former he would be examined by two ordained surveyors, appointed annually by the Town Council for the purpose. If, however, he applied to the sheriff, the candidate could choose his own examiners.

The society should have, I think, a good effect upon the profession, especially as it ensures the proper conduct of the qualifying examinations, and quantity surveying is a profession which requires such examinations, for it will be seen that much injustice could be done through incompetency on the part of a surveyor.

Church Crafts League. — The Bishop of Rochester presided over the first annual general meeting of the above society on Tuesday evening last week at Bishop's House, Kennington Park, S.E. In moving the adoption of the annual report, his lordship made reference to the steady progress the League had made, in spite of the many difficulties which attended a new society in this already overcrowded age. At the inaugural meeting in February last, the League had 29 artist and 35 ordinary members. The membership has now been raised to 164, of whom 43 are artist members. After the formal business of the meeting had been transacted, an interesting discussion was raised on the objects and aims of the League. Mr. T. Stirling Lee reminded his hearers that since the time of Henry the Eighth the divorce of art from religion had been absolute. Canon Rhodes Briston, Mr. Henry Holiday, and the Rev. Percy Dearmer also took part in the discussion. The Rev. C. R. D. Biggs, vicar of St. Phillip and St. James', Oxford, announced that he had arranged for a meeting to be held in Oxford to explain the methods and aims of the League.

Professional Practice.

Leamington.—The foundation stone of the new Leamington Free Library and Technical School was laid recently. The site has a frontage on the south to Avenue Road, on the west to the newly-constructed thoroughfare leading from the Avenue Road along the upper portion of the Pump Room grounds, and overlooks the Leam. The building will contain three floors, a lower ground floor, a ground floor, and a first floor. The lower ground floor will face entirely to the north. It will contain a room for manual instruction. The Free Library is placed altogether on the ground floor. The main entrance will be from Avenue Road. The northern side of the building will be taken up by a range of seven class-rooms belonging to the Art and Technical School, and by a room for the secretary, each of which will be separately approached by a corridor running from east to west. Movable screens will enable the class-rooms to be used separately or collectively as desired. The first floor will be occupied entirely by rooms set apart for the teaching of art and science subjects, with the exception of two rooms set apart for instruction in cookery and laundry work respectively. The art rooms will occupy the whole of the northern part of the building, and will be 10ft. long by 20ft. wide. The Free Library and the Art and Technical School, although under one roof, are to be kept entirely distinct and separate. The only public entrance to the Free Library will be in the centre of the south front and approached from Avenue Road. The entrances to the Art and Technical School are to be on the eastern and western sides, one for male and the other for female students. The building will be warmed throughout by hot water upon the low pressure system, having radiators placed in the most convenient positions, each of which will be capable of individual control. Ventilation will be effected by the admission of fresh filtered air from the outside passing through the gills of the radiators, while the foul or vitiated air will be drawn through openings in the walls and ceilings into the main extract shaft fixed in the turret over the lecture room. The style adopted is a free treatment of the Renaissance. The entrance to the Free Library from the Avenue Road will be flanked by pilasters and heavily canopied. Above, in the main gable of the building, will be the main windows of the lecture hall. The centre gable will be flanked on either side by gables of minor importance having semi-circular pediments. Similar gables and dormer windows will break the façade of the north elevation fronting the Pump Room Grounds. The building throughout will be faced with pressed bricks from the Cherry Orchard Yard, enriched by mouldings and by heads, cills, mullions, transomes, pediments, cornices, &c., of terra cotta, supplied by the Hathern Station Terra Cotta Company. Westmorland green slates will be used for covering the several roofs, where these are not of glass. The contract for the whole building, amounting to about £16,000, has been let to Mr. Richard Bowen of Tavistock Street, and the clerk of the works appointed by the Town Council is Mr. E. Atkins, of Grove Street. Mr. J. N. Bottomley is the architect.

London, W.C.—De Keyser's Royal Hotel, Victoria Embankment, is undergoing considerable alterations. The former courtyard of the hotel is being converted into a lounge, 54ft. by 62 feet long. The central dome will be 40ft. in diameter, the height from the ground being 32ft. and supported by Languedoc marble, 16ft. high. The vases are panelled with alabaster. The marbles that go to make up the scheme of decoration include grand antique from Belgium, Languedoc from the South of France, Piastraccia marble from Italy, and alabaster from Staffordshire. Above the dome there will be a smaller one, and the height from the ground to the top of this crown will be 40ft. The remainder of the decoration of the lounge will include an alabaster dado, and an enriched cornice of the same stone. The addition which will be made to the dining-room of the present corridor, where the entrance to the billiard room formerly existed, will enable guests to dine within full view of the lounge. The scheme of alterations covers an area of 12,800ft. Provision has also been made for new offices, the reception office itself measuring 34ft. by 15ft., while the roof will be supported on four columns of the same marble. The lounge, when completed, will be the largest in London. One great advantage it will possess will be that no artificial light will be used there in the daytime, as not only will the dome be of suitable glass, but the space between will have 14 dominal lights, dome-shaped, and 19ft. from the floor. The construction of this apartment will lead to the enlargement of offices in close proximity. Visitors to the hotel will in future be received in an outer hall, 70ft. by 25ft., which will be decorated in the same way as the lounge. The roof will be supported on six octagonal marble columns, and the whole of the dado, walls and cornice will be of alabaster. In order to keep the whole of this hall, and also the lounge, free from any draught, two Vankanell revolving doors of Spanish mahogany, with carved capitals and pilasters, will be made use of. Mr. E. Gruning is the architect, and is assisted by Mr. A. Pelley. The builders are Messrs. Holland and Hannen.

Newcastle.—Bensham, Gateshead.—The foundation stone of the new church of St. Chad, at Bensham, Gateshead, was laid last week. The church is to be built entirely of stone, and is designed in the style which prevailed at the early part of the 15th century. The whole of the roofs, doors, and internal wood fittings are to be of oak, and the wood block flooring of teak. The plan consists of a lofty nave and chancel, north and south aisles, transepts, chancel aisle, morning chapel, clergy and choir vestries, organ chamber, porches, &c. The chancel does not terminate in the usual way with a blank wall at the east end, but with three arches which open on to the morning chapel, which is 28ft. in length and 15ft. 6in. in width. The total length of the church, including morning chapel, is 150ft. The feature of the church internally and externally will be the central octagonal tower springing from lofty arches at the crossing between nave and transepts. Its panelled and moulded ceiling will be ornamented with carved bosses and wooden groining. Externally, the tower will be crowned with pinnacles and traceries, and battlemented parapet. Sitting accommodation will be provided for 650, but with ample floor space many more could be seated on great occasions. A spacious cellar is provided below the west end of the church for heating purposes. The contractor for the work is Mr. Isaac Bewley, of Dunston, and Messrs. Hicks and Charlewood, of Newcastle, are the architects.

West Hartlepool.—A church, with large hall, classrooms, and caretaker's house, was designed for the Park Road congregation of the Presbyterians of West Hartlepool by Messrs. Badenoch and Bruce, architects, of Newcastle, and their plans were approved by the local building committee. The foundation stone of the hall was laid on March 3rd of this year, and the hall and a front block of buildings have now been completed. These buildings were publicly opened last week. The new buildings are of brick, with stone dressings, the principal front being faced with red pressed Commondale bricks. The block facing Sandringham Road has an entrance hall, a staircase, lavatory accommodation, secretary's room, a library, and a large infant-classroom on ground floor; session room, ladies' room, lavatories, and access to hall gallery on the first floor. The stairs are fireproof, and have ample landing room. The hall is placed behind the front block. It is about 51ft. long by 39ft. wide, and 29ft. high to ceiling, having a gallery at one end. The roof is open-timbered up to collars, and is of selected pitch-pine, with similar ceiling, cleading and mouldings; and a pitch-pine dado is carried all round the hall on ground and gallery floors. The gallery, and under same, is divided into classrooms, with heavy woollen curtains. Behind the hall a corridor leads to a large kitchen for tea meetings, with heating chamber under and back exit to Angus Street. The hall is ventilated with "Climax" concealed roof ventilators and "Sherrington" inlets, additional summer ventilation being provided by hopper-

sashes in the windows. The heating is by low-pressure hot water, with pipes and radiators. The lighting is by electricity, with supplementary gas-jets for emergencies. The general contractor is Mr. William Pearson, of Burn Road, West Hartlepool; the heating apparatus is by Messrs. Dinning and Cooke, the electric lighting by Messrs. Thomas G. Usher and Co., and the lead-glazing is by Messrs. Atkinson Bros., all of Newcastle-on-Tyne.

New Patents.

These patents are open to opposition until December 31st.

1899.—Valves for Cisterns and Tanks.—21,493. F. J. BRAZIER, 56 Seven Sisters Road, Holloway, London, N. The float is not fixed at the end of a lever, but is free to slide up and down a vertical tube attached to the water-supply pipe. Levers attached to the float at each side operate the valve at the bottom of the tube. It is claimed that the water enters without noise, that the device can be fixed in very small cisterns, and that it is simple in construction and operation.

Automatic Bricklaying.—21,823. J. H. KNIGHT, Barfield, Farnham, Surrey. At each corner of the building to be built an iron or wooden post is erected. Between two of these a beam stretches, capable of being fixed at any height on the posts and having a rack on its upper side. Working on the rack is the bricklaying machine proper, this consisting of a frame carrying a pinion and a lever; the bricks are fed to it by hand and the laying of both mortar and bricks is then done automatically. A guide board acts as a straight edge for setting the bricks and window or door openings are provided for by substituting for bricks suitable pieces of wood or metal, which are afterwards removed.

Sanding Brick-Moulds.—25,338. E. T. BENNETT and J. BRENNAN, Towanda, Pennsylvania, U.S.A. The invention consists of certain features of construction by which the mould, after being sanded, is automatically inverted and rapped, so that the surplus sand is removed; and also of a mechanism for feeding the mould direct to the moulding machine. The sanding is accomplished very rapidly.

Brickmaking Machines.—25,540. T. C. FAWCETT, LIMITED, and J. D. FAWCETT, Whitehouse Engineering Works, Hunslet Road, Leeds. This invention relates to wire-cut brickmaking machines. It consists in the combination of a hinged stop plate or movable end piece, link, lever, weighted spindle, and stop piece, all arranged so as to be simple and effective in action.

1900.—Band Saws.—487. J. W. KING, 19 St. Leonard's Avenue, Bedford. The wheels carrying the saw each have a recess in the centre of the rim, in which a seating of india-rubber or other flexible material is fixed. The material projects slightly above the surface of the rim, and is a little narrower in width than the saw. The feature of the invention is that the wheels used run on parallel axes.

Broken Stone Paving Material.—13,169. J. WARD, Northern Quarries Company, Grange-over-Sands, Lancashire. The rock or stone is fed to the crushers, screened, and mixed with tar—whilst in a dry and warm state. By this means the full capacity of the machines is obtained whatever the weather may be, and the stone is more evenly covered with the tar.

The following specifications were published on Saturday last, and are open to opposition until January 7th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—21,707, HOWATH, coal saver for attaching to firegrates. 21,889, THOMPSON (*Rech*), theodolites and similar measuring instruments. 22,104, BODGER AND HANDFORD, guards for circular saws. 22,459, CHARLES MURRAY FORD, cheeks of hopper windows. 22,605, DOULTON, valve water-closets. 22,631, WAYLAN, plumbers' shave-hook. 22,647, FISHER, windows. 22,926, GREEN, chimney tops for preventing down-draught. 24,310, BEAUMONT, coin freed appliances for locks or fasteners of lavatories. 25,214, SELLARS, manufacture of hollow building blocks and tiles. 25,430, BULLIVANT, pulley blocks. 25,516, HADFIELD AND JACK, crushing machines. 25,590, LAKE (*Röper*), registering devices for use in connection with hoisting apparatus.

1900.—129, HARVEY, dusting and sweeping apparatus. 151, KESSELRING AND RÖTHENBACHER, traps or syphons for drains. 1,803, CHANT, construction of fireproof floors and ceilings. 3,995, PLACE, construction of mantles for incandescent gas light. 5,997, MADAN, shower baths. 9,152, EVANS (*Faller and Chisholm*), manholes. 10,168, MILBURN, chimney cowls. 11,442, RECTOR, portable houses. 11,874, THOMPSON (*Simonini*), lighters for gases. 13,275, GOULDING, device for raising and lowering the gratings of cooking ranges or stoves. 13,942, VANDERMAN, couplings for sewer and other pipes. 13,996, LUCAS-GIRARDVILLE, apparatus for the production of acetylene gas. 14,114, KLEE, emulsion for removing paints and varnishes. 15,292, TITUS, production of acetylene gas. 15,568, EINFELDT, construction of buildings. 15,939, TYLER, mitering machines. 16,367, REES AND BOUNDY, generators for acetylene gas. 17,050, LAKE (*Cunningham*), universal joints. 17,343, DOUGILL, adjustable spanners. 17,546, WELCH, external shop lanterns. 17,548, COLLINS, ceiling lamps. 17,557, KING, cold-water paint.

Law Cases.

What is Rubbish?—The case of *Benjafield* v. *Wall* was heard in the Queen's Bench Division of the High Court of Justice on November 21st. This was an action for damages for breach of contract for delivery and carting away of material from the archway at Highgate. The plaintiff was the executrix of the late Allen Albin Benjafield, who, in his contract with the defendant, had made use of the word "rubbish," and in the course of the carting the meaning of the term "rubbish" was raised, the plaintiff alleging that in the building trade it was always used in the sense of "brick rubbish and hard core." The defendant, Charles Wall, denied that it had that meaning. The President, in delivering judgment, said that he was satisfied that both parties had honestly believed that the view each had held was the true view that ought to be adopted in construing the contract that had been made between them. The preponderance of evidence, however, was in favour of the defendant's contention, namely, that "rubbish" meant that which was *per se* inherently useless. There would, therefore, be judgment for the defendant with costs.

Disregarding the By-laws.—At Brighton recently a greengrocer named Luxford was the defendant in three adjourned summonses issued by the Corporation, for infringements of the building by-laws. One was for erecting a new building without delivering proper plans to the surveyor, another was for building an addition to his premises beyond the main front wall without the consent of the Town Council, and the third was for erecting a new building nearer to the centre of the street than the prescribed line of frontage. Mr. Hugo Talbot, Deputy Town Clerk, said defendant had erected a building in front of his shop covering the whole of the forecourt. There was no doubt there were many similar buildings in the Gardens; they ought not to be there; but some of them were erected before the Corporation had the power to deal with this sort of thing, and others had grown up gradually, little by little, unobserved. In this case he relied upon the definition of a building contained in the Improvement Act, and maintained that the case was not only within the letter but the spirit of the by-law. It was very regrettable that these buildings had in the past been allowed to come into existence, for they very seriously obstructed the Gardens. The Stipendiary thought it might have been arranged that the summons should be withdrawn on payment of costs and defendant promising to remove the structure. Mr. Talbot said he was afraid the Council would not approve of this course being adopted. A nominal penalty of 5s. and costs was accordingly imposed. The other two summonses were adjourned until the 30th inst.

Water Supply in Brickmaking.—At the Chichester County Court the case of *Hayter* v. *Tate* was recently heard. This was a claim for £1 11s. 1d. in respect of retention-money, at the rate of 3d. per 1,000 bricks, on a brickmaking job. The plaintiff, it appeared, had been employed as a brickmaker under an agreement at the brickyard of the defendant, Mr. W. Tate, the rate of payment being 5s. 9d. per 1,000, with 3d. retained until the end of the season. After working for some weeks, the plaintiff left because, as he alleged, the defendant wanted to break his contract by deducting 1d. per 1,000 in respect of water laid on from the company's mains when the well in the yard failed. He accordingly now sued for his retention-money. Plaintiff called Mr. Geall, brickyard proprietor, with a view to prove that the charge of 1d. per 1,000 for water was not customary and that he never enforced it at his own yard. For the defence, however, it was contended that the charge of 1d. was a customary one and that the fact was well known to the plaintiff, who was dealt with on exactly the same conditions as the other moulders employed in the yard. Evidence was given for the defence showing that when the water was laid on from the mains the plaintiff was informed that the conditions would be the same as formerly. The charge for water had, it appeared, been made four years previously when the plaintiff was in Mr. Tate's employ, and two of the moulders, Alfred Novis and James Stallard, stated that the plaintiff was fully aware of the conditions. The charge was made because the water was for the benefit and advantage of the men in their work. His Honour decided that the plaintiff had broken his contract by leaving before the end of the season and must therefore forfeit his retention-money. Judgment was accordingly given for the defendant.

Trades Unions: Can they be Sued or Not?—On Wednesday last a decision was arrived at in the Court of Appeal in the case of the *Taff Vale Railway Company* v. the *Amalgamated Society of Railway Servants* and others. This was an appeal by the Society from the refusal of Mr. Justice Farwell to order that they should be struck off the record as defendants in an action brought by the railway company. The Master of the Rolls said this was an action against a trade union in its registered name, and against Richard Bell, M.P., and James Holmes, officers of the union, for unlawful picketing, and it claimed an injunction and other relief, which would include a claim for damages. No question upon this appeal arose as to the competency of the action against Mr. Bell and Mr. Holmes; the point made was that this action was not maintainable against the trade union. The point was important, for if a trade union could be sued in the manner proposed the funds of the union would be liable to be taken in execution under a judgment obtained against the union in the Society's name. In the Companies Act of 1862 it was expressly provided that a registered company could be sued. The same provision was to be found in the Building Societies Act of 1854 and in the Industrial Provident Act of 1893. But the Court failed to see any such provision in the Trades Union Acts. Mr. Justice Farwell did not suggest in his judgment that in the Trades Union Acts he could find any sections in terms authorising an action against a trade union in its registered name, nor that, by the Acts, trade unions were incorporated; but the learned judge said that the Legislature had legalised it (i.e., the trade union), and it must be dealt with by the Courts according to the intention of the Legislature. As there was no statute empowering the action to be brought against a trade union in its registered name it was not maintainable against the Amalgamated Society of Railway Servants, and these defendants, concluded his lordship, "must therefore be struck out, the injunction against them must be dissolved, and the appeal as regards

these defendants must be allowed with costs here and below." The rest of their lordships concurred.

Builders' Bankruptcies: An Important Decision.—At the Sunderland County Court on Thursday last His Honour Judge Meynell gave judgment in the motion made at last month's court by the trustee of W. H. Brown, builder, a bankrupt, claiming (1) payment from the Athenæum Buildings Company, Limited, of £218 7s. 6d., the value of material, plant, &c., which belonged to the bankrupt, and was upon the new Athenæum Buildings in Fawcett Street, Sunderland, and which was taken possession of by the company when the bankrupt disappeared in November, 1899; and (2) payment of £58 17s., the value of dressed stone which was in the bankrupt's stoneyard in Holmeside, and was also taken possession of by the company in November, 1899. The facts are:—Brown contracted with the company to build the new Athenæum Buildings in Fawcett Street. The contract authorised the company to terminate it if the works were not duly proceeded with, and also empowered the company to take possession of and use all the plant, material, &c., upon the works should Brown become bankrupt or should the company have to exercise their power to terminate the contract, &c. Brown disappeared about the 10th of November, 1899; on the 22nd of November the company gave notice to terminate the contract, and on the 18th, 20th, and 21st November a quantity of dressed stone, intended for the Athenæum Buildings, was removed from Brown's stoneyard to the buildings in Fawcett Street by order of Mr. Eltringham, the company's architect; on the 28th November the company took possession of their buildings and everything thereon, and on the 15th of December, 1899, Brown was made bankrupt. After referring to the facts and to the law as argued by counsel on both sides at last month's Court, the Judge held that the contention of the Athenæum Buildings Company as to the claim for £218 7s. 6d. was right, and therefore refused the trustee's application as to that sum; but he considered that the company had no power to seize the dressed stone on the Holmeside ground, and therefore gave judgment for the trustee for £58 17s.; but as both sides had been partially successful he gave no costs, but said the trustee could have his costs out of the bankrupt's estate.

Surveying and Sanitary Notes.

The Westminster Improvement.—The Westminster City Council Finance Committee are considering the advisability of making a contribution of £100,000 towards the projected improvement of Millbank.

The Coal Smoke Abatement Society.—H.R.H. The Princess Louise (Duchess of Argyll), has, states the "Public Health Engineer," been graciously pleased to join the committee of this society, with the objects of which she deeply sympathises.

Proposed Improvement at Manchester.—The Manchester City Properties Company is one which proposes to purchase the whole of the area bounded by Market Street, New Brown Street, Cannon Street and Corporation Street. This space is covered by buildings used for business purposes, and is intersected by a number of narrow streets. The property is old, and the fabric does not boast of any particular architectural pretensions, but the land itself, as it abuts upon Market Street, the principal business thoroughfare, is of enormous value. The company, in case it is successfully formed, intends to raze all the existing buildings to the ground and to replace them with property of a more ornamental character. It is also proposed to cut two important streets through the land from opposite corners, and, of course, crossing in the centre of the area, the buildings thus being in the shape of a Maltese cross. It is suggested that the buildings in the proposed new streets should be erected on the principle of the "rows" in Chester, and that they should be six storeys high. This would, under usual regulations of course, mean that the street would have to be of great breadth, as according to the city by-laws, the height of a building must not be greater than two and a half times the width of the street upon which it has its frontage. There is, however, a clause in the prospectus of the company seeking to set aside or alter the provisions of Acts relating to buildings and streets. It is estimated that the cost of the scheme will amount to £1,500,000. Messrs. W. Telford Gunson and Son, architects, of Manchester, have prepared the plans.

Keystones.

Six Church Homes at Ealing have been erected.

The Restoration of Wilby Church, near Attleborough, is proposed.

Colton St. Andrew Church, near Wymondham, has just had a new stained-glass window added.

A New Board School at Grimsby is to be erected in Harold Street, subject to the approval of the Education Board.

The Church of the Good Shepherd, Lake, has had a new stained-glass window added. The window is the work of Mr. E. Frampton, of Buckingham Palace Road, London.

The Purchase of Alexandra Palace and Park in the public interest has now been completed at a cost of £138,000. The total amount subscribed has been £150,120, but the balance will be required to reinstate the buildings and park.

The New Military Barracks at Crownhill, near Plymouth, which have been erected on the hutment principle, are now ready for occupation. The barracks, which comprise fifty distinct buildings, provide accommodation for 1,000 officers and men.

A Fire at Oak House, West Bromwich, occurred last week. This old Elizabethan building was used by the town as a museum and art gallery. The fire, it is stated, originated through a defective flue. The middle turret of the building was destroyed, but all the pictures and curios were saved.

People's Baths for Liverpool.—The baths committee of the Liverpool City Council have adopted the plans, specifications, and quantities for the first proposed people's baths along the line of docks, in Beacon Street, referred to on p. 288 of our issue for November 14th. The finance committee are to be asked to sanction the expenditure.

Isolation of the National Gallery.—Steps are at last being taken, hastened no doubt by the recent fire in Pall Mall East, to isolate the buildings of the National Gallery, on the north side of Trafalgar Square, the Commissioners of her Majesty's Works and Public Buildings giving notice that application is intended to be made in Parliament in the Session for an Act authorising them to acquire by compulsory purchase or otherwise certain lands, houses, and buildings adjacent to the west side of the Gallery.

British School in Rome.—The managing committee announce that the school will open in December. The director, Mr. G. Rushforth, is on his way to Rome. Communications to him should be addressed, "G. McN. Rushforth, Esq., the British Embassy, Rome." Intending students are requested to apply to Professor Pelham, Trinity College, Oxford, from whom all particulars as to admission, &c., can be obtained. The school is intended to promote the study, not only of classical history and archæology, but of mediæval history, art, and literature. The director will be happy to explain the principal recent discoveries relating to ancient and mediæval Rome to any University graduates and members of the teaching staff of public schools who may be visiting Rome during the Christmas or Easter vacations. Those who wish to avail themselves of this offer are requested to communicate with the director as soon as possible. Should there be any expenses connected with the lectures, a small fee may be asked for.

A new Church at Chapel Allerton, Leeds, has been erected at a cost of £20,377.

A new Church at Eaglescliffe Junction, Holy Trinity, Stockton, is to be erected.

St. Lawrence's Church, Brundall, has been enlarged by the addition of a new north aisle of three bays, with a vestry at the eastern end.

A new Presbyterian Church at West Kilburn is to be erected at a cost of £5,000 on a site secured from the Ecclesiastical Commissioners.

The new Church Tower of St. Nicholas, Henstridge, which has been erected at a cost of £2,000, was opened last week. Six new bells were also dedicated.

The death is announced of Mr. W. Law Bros at the age of 55. The deceased contributed several articles to our columns upon Istria and Dalmatia, and was an authority upon the rude stone monuments of the Skelligs, and upon the coast of Ireland generally.

The Roman Pavement at Dorchester, which was recently discovered, has been purchased by Mr. Alfred Pope, a member of the Dorset Antiquarian Society, who has presented it to the Dorset County Museum. It will be taken up at once and laid in the institution.

The Royal Academy Students' Club will hold a smoking concert at the Suffolk Street Galleries on December 8th. Sir Lawrence Alma-Tadema has consented to occupy the chair. Tickets can be obtained from Mr. A. R. Jemmett, of 21 Great College Street, Westminster, S.W.

Guildford Town Hall: A Correction.—On page 310 of our last issue we stated, on the authority of a trustworthy correspondent, that Guildford Town Hall was to be pulled down. We now learn, however, that it is Godalming Town Hall which is to be demolished. We regret the error.

The Musselburgh New Municipal Buildings Competition.—The Town Council have awarded, on the recommendation of Mr. George Simpson, F.S.I., of Leith, the assessor, the first premium of £25 to Mr. William Constable, of Musselburgh, and the second of £15 to Messrs. Findlay and Roques, of Edinburgh and London.

For the New Infirmary, Bristol, the following have been selected to compete:—Messrs. Crisp and Oatley, W. L. Bernard, W. L. Gough, W. S. Shurmer Williams, Frank Wills, and F. Bligh Bond, all of Bristol; C. W. Bevis, of Portsmouth; Arthur Marshall, of Nottingham; and A. and C. Harston, H. Percy Adams, Giles, Gough and Trollope, and Newman and Newman, all of London. The infirmary is to accommodate 1,000 of the sick poor of the City and County of Bristol.

A Meeting of the Architectural Association was held last Friday, Mr. W. H. Seth-Smith, president, in the chair. The following gentlemen were elected members:—Messrs. R. P Jones, J. F. McIlwraith, P. W. Mulready, J. M. Pilkington and S. N. Simmons. Mr. A. T. Walmisley read a paper on "The Use of Rolled Steel Joists in Construction," which will be published in our next issue. The members of the Institution of Junior Engineers having been invited to attend the meeting, a long discussion took place.

A Sale of Works by William Blake took place last week at Messrs. Puttick and Simpson's rooms, Leicester Square, W.C. The two lots consisted of four rare and curious books by the poet and artist. The first lot consisted of "Europe a Prophecy," with seventeen designs coloured by the author, with two original water-colour drawings by Blake added, Lambeth, 1794—"The Song of Los," five designs, coloured, and one water-colour drawing, 1795, and "Visions of the Daughters of Albion," six leaves with coloured designs, 1793, all in one volume, half-bound. The bidding started at £10, and after a keen competition the lot was secured by Mr. Quaritch for £225. Blake's "The Book of Thel," eight leaves with coloured designs by the author, in wrappers, uncut, 1789, went for £46, also to Mr. Quaritch. The last copy of "Europe" alone sold by auction for £59: the "Daughters of Albion" for £20 5s. No copy of the "Song of Los" appears to have been previously offered.

New Companies.

Wallis and Stevens Auxiliary, Limited.

This company was registered on November 9th with a capital of £5,000 in £1 shares to acquire land on the Cliddesden Road, Basingstoke, to lay out such land for building purposes, to make roads, to build houses, shops and conveniences, to let or otherwise dispose of the same, &c. Registered office: North Hants Ironworks, Station Hill, Basingstoke, Hampshire.

J. and A. J. Brown, Limited.

This company was registered on November 8th with a capital of £5,000 in £1 shares to acquire the business carried on at West Hartlepool, Durham, as Brown Brothers and Co., and to carry on the business of cabinet makers, upholsterers, joiners, timber merchants, &c. The first directors (to number not less than three nor more than five) are J. Brown and A. J. Brown (managing directors), and others to be appointed by the subscribers.

The Acomb Wesleyan Chapel, Hexham, has just been re-opened after having been thoroughly renovated and re-seated with pitch-pine seats from designs by T. Leslie Anderson, M.S.A., of 11, Royal Arcade, Newcastle-on-Tyne.

Carshalton New Hospital.—The Metropolitan Asylums Board have adopted the recommendation of the Works Committee, that the revised estimate of the proposed cost of erecting, fitting up, and furnishing a new hospital at Carshalton, to be called the Southern Hospital, be approved and accepted, and that the Local Government Board be asked to issue an order authorising the managers to expend and borrow a sum of £284,312 for the purpose.

New Asylum for Surrey.—The Surrey County Council at Kingston-on-Thames have decided to build a new lunatic asylum on the Netherne Estate, in the eastern part of the county, at an estimated cost of £300,000. The present asylum at Brookwood has long been overcrowded. The proposed new asylum will take 960 patients. Separate provision is being made for possibly curable cases, for idiot and imbecile children, for working patients, and for the general class of lunatics.

CONTRACTS OPEN.

THE URBAN DISTRICT COUNCIL of WALKER invite TENDERS for the ERECTION, complete, of the BUILDINGS, FLUES, and CHIMNEY for a 2-unit Refuse Destructor, which will subsequently be erected under another contract.

The whole of the works to be in strict accordance with the specifications prepared by the Engineers. The specifications are in two parts:—

1. Chimney and External Flues. 2. Buildings comprising Destructor House.

The contract to be entered into will be subject to the approval of the Local Government Board. Firms desirous of tendering must send in their names to the Engineers, Messrs. HANDCOCK & DYKES, 1 Victoria Street, Westminster, London, S.W., together with the sum of Two Guineas (returnable on receipt of a bonâ-fide Tender). The Engineers will then forward a copy of the specifications and quantities, and on production of same the plans may be inspected at the Council Chambers, Church Street, Walker.

Tenders, under cover, marked "Buildings," must be delivered to the undersigned on or before DECEMBER 8th, 1900.

T. M. STURGESS,
Clerk to the Walker Urban District Council.

November, 1900.

HEADINGTON RURAL DISTRICT COUNCIL.
HOLTON BRIDGE.

The above Council are desirous of receiving TENDERS for the TAKING-DOWN and RE-BUILDING of the SOUTHERN PORTION of this BRIDGE, as indicated on plans; also for the CONSTRUCTION and MAINTENANCE of a TEMPORARY BRIDGE so as to divert the traffic during the progress of the works. Such plans and specifications can be seen at my office, No. 126 High Street, Oxford. Further information can be obtained of, and the Bridge can be viewed by appointment with, Mr. LEE TURNER, Surveyor to the Council, of Hartfield Cottage, New Headington, Oxon.

Tenders, endorsed "Holton Bridge," must be received at my Office above mentioned not later than TUESDAY, the 18th day of DECEMBER, 1900.

The Council do not bind themselves to accept the lowest or any Tender.

By order of the Council,
THOMAS W. MALLAM,
Clerk.

No. 126 High Street, Oxford,
November, 1900.

TO BUILDERS and OTHERS.

The Metropolitan Asylums Board are prepared to receive TENDERS for the EXECUTION of certain STRUCTURAL ALTERATIONS, PAINTING, and other Works, at Rochester House, Little Ealing, W., in accordance with specification and plans prepared by the Surveyor to the Board, and to be seen upon application at the Office of the Board.

Printed Forms, upon which alone Tenders will be received, together with copies of the bills of quantities, may be obtained at the Office of the Board, Embankment, E.C. (corner of Carmelite Street), upon payment of a deposit of £2 2s., returnable upon the receipt of a bonâ-fide Tender.

Tenders, sealed and endorsed "Tender for Structural Alterations, &c., Rochester House," are to be returned to the undersigned, together with the priced bills of quantities, before TEN a.m. on WEDNESDAY, DECEMBER 5th, 1900.

The Managers do not bind themselves to accept the lowest or any Tender.

By order,
T. DUNCOMBE MANN,
Clerk to the Board.

November, 1900.

ROMFORD SCHOOL BOARD.
TO BUILDERS AND CONTRACTORS.

The above Board are prepared to receive TENDERS for the ERECTION of an INFANT SCHOOL to accommodate 290 children.

Plans, specification, and conditions may be seen at the Albert Road School, Romford, between the hours of TWELVE and FOUR p.m., except on SATURDAYS.

Bills of quantities can be obtained at my Office on payment of Two Guineas, which will be returned on receipt of a bonâ-fide Tender.

Tenders, under seal, endorsed "Tender for Infants' School," must be delivered at my Office not later than TWELVE noon on MONDAY, the 10th day of DECEMBER next.

The person whose Tender is accepted must enter into a bond, with two responsible parties as sureties, in the sum of Five Hundred Pounds for the due performance of the contract.

The Board do not bind themselves to accept the lowest or any Tender.

By order,
WILLIAM SMITH,
Clerk.

No. 24 North Street, Romford,
November 1900.

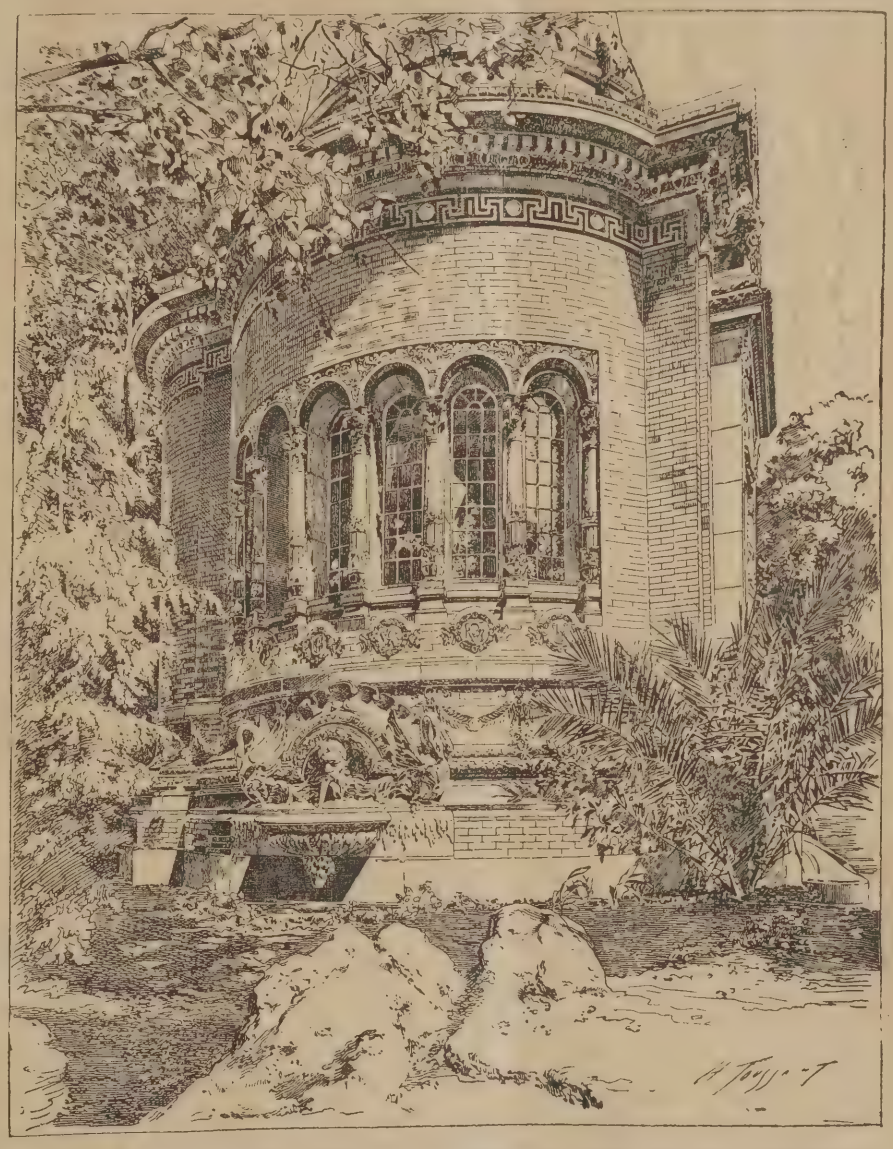
EFFINGHAM HOUSE, ARUNDEL STREET, STRAND, W.C.

An Architectural Causerie.



Eighteenth-Century Architects in France.

LADY DILKE'S book has drawn attention to a subject which can never cease to be of value, the architects and sculptors of France in the last century. Their influence is less no doubt than it once was; the Gothic revival, the more careful study of the past which sprang from it, the modern attempt to create a new style, and finally the lapse of a hundred years, have all tended to diminish it. In style—in mere style—we shall not again, perhaps, see their works taken as models; but the magnificent central part of Paris owes more to them than is generally known; if the late Emperor and Baron Haussmann rebuilt on a great scale, they had to take the creations of their predecessors as starting points; for the late seventeenth and the whole of the eighteenth century were occupied in the construction of public works. The names of the French architects of that period are known but they do not linger much in the public mind. How many educated Englishmen in crossing the Place de la Concorde know that the two buildings which form the entrance to the Rue Royale are the work of Gabriel? Yet how simple, stately, and appropriate they are, and what would that splendid square be without them? To him, also, the lesser Trianon is due; and it might be described as an English country house in the park of a French palace. The great front of S. Sulpice, with its two towers, was the work of Servandoni, a man who was for some time a scene-painter in London, an occupation which is certainly favourable to the artist and architect and calculated to promote boldness and breadth of treatment.

The Madeline, though completed by Vignon early in the present century, was begun in the last by Constant d'Ivry, and continued by Conture. The magnificent triumphal arch called the Arc de l'Etoile was designed by Chalgrin in 1806, but its style is that of the preceding century. The portico of the Chamber of Deputies, with its twelve Corinthian columns, approached by wide stairs and surmounted by a large pediment enclosing sculpture, is by Royet. The Pantheon is the work of Soufflot. These are but a few of the men who adorned Paris in the last century or the very earliest years of the present. The great provincial cities of France owe much to the eighteenth-century architects. Nancy, the old capital of Lorraine, is a remarkable instance of a city grandly and spaciously designed; its Place Stanislas and other works are monumental. Bordeaux and Lyons, both very stately cities, laid the foundations of their splendour in the late seventeenth century, and their development went on during the eighteenth, preparing the way for the great rebuilding of our own day. To harmonise the old and the new, to preserve what is best in the works of the past, to design new streets and open spaces so as to produce a grand total effect, is the problem presented to modern builders, but nowhere has it been so satisfactorily solved as in France, for the eighteenth-century men gave a clear lead which their pupils and successors faithfully followed. Of the sculptors of the time the same may be said, for nothing is more remarkable than the manner in which they played into the hands of the architects throughout the century.

Trafalgar Square.

IT is stated that alterations are to be made to the fountains in Trafalgar Square. The notion has often been conceived that some greenery should be introduced into the present expanse of granite and asphalt, but no attempt worth mentioning has been made to effect such a change. Water never looks so well as when it is surrounded by verdure, and the idea to obtain such an effect in London's great square is worthy of consideration. The whole of the space around the fountains and pedestals which now looks so cold and barren might be covered with turf up to the row of pillars on the south side, a pathway being left at each side to afford communication with the steps. Such a treatment would enhance the appearance of the square and would form an elegant foreground to the National Gallery. At present the space is mostly frequented by the unemployed. By enclosing it, and laying down grass in the manner suggested, the only persons seriously inconvenienced would be those who have chosen the spot as a rendezvous for the discussion of grievances.

PAVILION OF THE TOURING CLUB, PARIS EXHIBITION, 1900. M. RIVES, ARCHITECT

St. Martin's Steps.

NOTWITHSTANDING all the hostile criticism of the proposal to alter the steps of St. Martin's Church, the Improvements Committee of the London County Council remain obdurate. When the recommendation was considered a few weeks ago Mr. Shaw-Lefevre managed to defer it by a resolution that the Council should take expert architectural advice before coming to a decision. This advice was sought of the Institute who, we think, have not made a sufficiently strong protest against this ill-conceived scheme. The Institute agree that the removal of the landing would be very detrimental to the appearance of the church, but they give the Committee a handle by suggesting that if such a removal were an actual necessity (which, however, they do not admit), the landing might be removed on the west side and allowed to remain on the south side. This arrangement would be of little help in preserving "somewhat of a symmetrical appearance to the base of the portico," because the length of the landing on the south side is only about a fifth of that on the west side. Such a semblance of acquiescence on the part of the Institute is sufficient to keep the Improvements Committee's spirit alive, despite the fact that their recommendation was rejected at last meeting of the Council, and their precedent may still be followed by the Westminster Council. The alteration would add a meagre width of 2ft. 6in. to the pavement, but it would spoil the western setting of this fine church. After this inadequate show of opposition to the scheme, the Institute branch off and suggest that the cast-iron railings now fixed between the columns should be removed, a proposal which the Improvements Committee think most undesirable. But this is a side issue which there was no need to raise while the main question was unsettled.

DECORATION OF ST. JAMES'S CHURCH, BERMONDSEY.

BY H. K. D.

THE Church of St. James, Spa Road, Bermondsey, S.E., has recently undergone renovation and redecoration, and was reopened last month. The church is comparatively a modern one, as the first stone was laid on May 21st, 1827, the building being consecrated just two years later. It was designed by James Savage—the well-known architect of the church of St. Luke, Chelsea, and of numerous additions and reconstructions in the Middle Temple—and G. Allen. The church is Classic in style ("Grecian" we are told in the contemporary accounts in "John Bull" and the "Gentleman's Magazine"), and is remarkable for its well-proportioned interior; it is altogether superior to the majority of the very poor buildings erected about that time in the name of architecture. The contract for its erection amounted to £21,412 19s. 5d., we are told, and the church accommodates about 2,000 persons. There appears to have been some considerable difficulty in finding a secure foundation in the marshy soil. The body of the church is of brick, with stone columns and dressings and a stone spire.

When the present renovation and decoration was undertaken, the building was in an extremely dirty and shabby condition, and the present vicar, the Rev. E. N. Coulthard, M.A., is to be commended for his energetic action in having this regrettable state of affairs remedied; he can now congratulate himself upon having obtained a very fine example of architectural decoration, the work of Mr. Arthur H. Ryan-Tenison, A.R.I.B.A., who has personally superintended the work.

With regard to the exterior, the stonework has been thoroughly repaired, not replaced, and much of the pointing of the brickwork renewed. The portico has been renovated and the iron frames of the windows repaired, repainted, and furnished with new ventilators. The heating apparatus has been much enlarged. The heating pipes should have been, if possible, hidden from sight under the old raised floor on which the benches are placed. Electric light has been installed, and the drop pendants, rococo in feeling, are light and undemonstrative. In the sanctuary incandescent lamps have been placed in grooves at the sides of the chancel arch, thus casting the light forward on the east end, without throwing the glare in the eyes of the congregation. This arrangement is shown in one of the illustrations. But it is the interior which has undergone the great transformation. It is now light and brightly impressive. The walls have been painted and treated simply with bands of stencilling, the order of their vertical arrangement being shown upon the reproduction given of Mr. Tenison's original first design. These stencils have very fitly been designed in no spirit of archæological pedantry, but are quite modern in feeling, the designs being natural enough to be clearly understood by inhabitants of that dingy neighbourhood—Bermondsey—yet sufficiently conventionalised to be decoratively suitable. The choice of the flower kingdom for the subjects of design is a happy one, when it is remembered that many of the poorer denizens of Bermondsey seldom, or never, see the green fields. It is, however, to be regretted that expense and the fear of giving the impression of a straining after higher ritual should have barred the introduction of the human form into the decoration, considering that there is a large painting at the east end, shown in one of the accompanying illustrations, filled with figures, and that the human body is a higher manifestation than the flower kingdom already used. Ornament must, of course, be conventional, but it need not be geometrical, and it is a great relief to the eye attuned to the perception of natural beauties – the basis of our artistic emotions—to see this very able attempt to break away from the *mélange* of our architect's stock-in-trade, so well known and so displeasing. Mr. Tenison has been most successful in his attempt to make the details interesting intrinsically as well as in their general bearing.

ST. JAMES'S CHURCH, BERMONDSEY:
GENERAL VIEW LOOKING TOWARDS SANCTUARY.

The general colour scheme is a harmony in green, given a piquancy by the cream-tinted Ionic columns, by touches of bright colour and by the design of the details, and as the caps of the columns are also whitened, a simplicity of line is obtained which the Ionic volute if made forcible would render less effective. The greens advance in a gentle gradation, beginning with a rich olive green in the dado of the nave walls, diminishing in strength until the clerestory is reached (where pale greenish buff is used), and merging into the roof, which is shaded in varying tints of greens and brown-greys, with the mouldings emphasised to give needed relief. This roof, on account of its light colouring, does not in any part give a feeling of oppression, but stands clear and high, materially aiding the general effect. The bands of stencilling are of various Biblical flowers and fruits, the band in the nave under the gallery showing the rose; in the gallery, first a band of the lily, and above it the apple; higher up, below the clerestory, tulips have been used as a motive for the frieze, and conventionally treated with the idea of suggesting mosaic rather than stencilling; and in the clerestory there is a pomegranate band, broken through by pilasters, whose constructive lines have of course been emphasised, with panels of the Tree of Life.

These stencil bands on the walls have been cut rather awkwardly by the openings, and it would have been better if the designs had been modified to fit in where necessary. The rose band on the nave wall has wavy curves dividing it into two halves, the lower one dark and the upper light—if anything slightly too light. The bands also have their lower lines cut objectionally by the doorways in the gallery. Just under the caps of the piers a necking band of stencilling is carried round, representing the daisy and grass of the field, emblematical of lowliness and humility of spirit, to illustrate the beatitude, "Blessed are the meek." These bands we suggest should have been omitted, weakened, or the ground made slightly darker. The curved front of the gallery, representing daffodils, is treated in deep rich yellows and brown greens, with a deep blue on the lower half. This blue needs to be gradated darker towards the bottom, for although not seen from the ground floor it is at once noticeable from the gallery. The stems of the daffodils running down through this blue well emphasize the fact, when viewed from an angle, that the front is curved. The text, one of the old landmarks, retained by special request we understand, is the least satisfactory feature in the scheme, but we are informed by the architect that he has the improving of this work already under consideration. The nave piers are a brown buff, with an oak-panelled base. The spandrels over the chancel arch are filled with a treatment of the poppy, the emblem of rest, encircling the Alpha and Omega in gold. The poppy is somewhat forcible, but time will, no doubt, soften its slight harshness. The treatment most suitable would have been to have filled the spandrels with draped figures, and the writer would suggest that James, the dedicatory saint of the church, and John, should be taken as the subjects for mosaics or paintings. The

west end is restfully painted a darker green than the general colour tone of the church.

Within the sanctuary the panels of the roof are treated with the olive branch and the passion flower, encircling the I.H.C. and the Greek X.P.C., and the sacred monogram, with the Tree of Life on either side of the picture and the daisy at its crown. The flanking walls have been panelled with stencils of the vine and corn, symbolical of the Sacrament, shown in the illustrations. Beneath the picture is a simple framework of oak panelling, almost entirely made from the book boards of the old seats once occupying the nave. The panelling should no doubt be returned on the flanking walls, but mural tablets which could not be moved prevented this being done. It also unfortunately had to enclose the Creed, the Lord's Prayer and the Commandments, which are surrounded by a conventionally-treated stencil, somewhat suggestive of Jesus' crown of thorns. The old picture at the east end is most destructive to an effective artistic treatment, dominating everything and looking like a hole in the wall, to say nothing of its intrinsic defects. It ought to be removed, but at all events the gaudy gold frame should be toned down to a green bronze. The floor is partially paved with mosaic having a neat fleur-de-lis design, unattractive of attention, as it should be. The dossal, a reredos it might almost be called, is of dark green stained oak, contrasting well with the lighter polished oak panelling behind. It has pewter tracery, a novel idea. The sanctuary railing is an old one, the original gates having been taken off; this, however, has left an unfinished ending for which the architect has designed a special-made thick banister not yet in place.

A choir has been formed in the body of the church, enclosed by oak screens and a dwarf-stone wall across the nave. The screens have clear leaded glazing, and on the north, as shown in the accompanying illustration, are arranged to form a morning chapel, as it might be called, for use at week-day services and classes, by drawing curtains across. A word should here be said as to the hangings. There are two small dull brown-green curtains to the choir stalls, and the curtains of the four small upper galleries or rooms, now disused, at the east and west ends of the gallery, and of the morning chapel, are of a pleasing red colour, all harmonising excellently with the scheme. The new oak choir stalls are the gift of Lord Llangattock of the Hendré—the new oak benches in the nave being a condition to his gift. The old benches still remain in the gallery, but those at the west end have been toned down to a mellow brownish red, and it now remains to complete the work round the sides. The pulpit has been made out of the oak from two old ones which used to stand on either side of the church, and stands on a stone pedestal. The staircase to it is from one of the old pulpits and will shortly have new turned balusters, the present ones being too frail in appearance. The carved panels of the choir stalls and pulpit are somewhat too conventional, but the funds in hand, we understand, only permitted of a very simple treatment.

The vestibule is also simply decorated, the wall up the staircase being coloured yellowish red, with a dark green band of stencilling, and a yellowish green above.

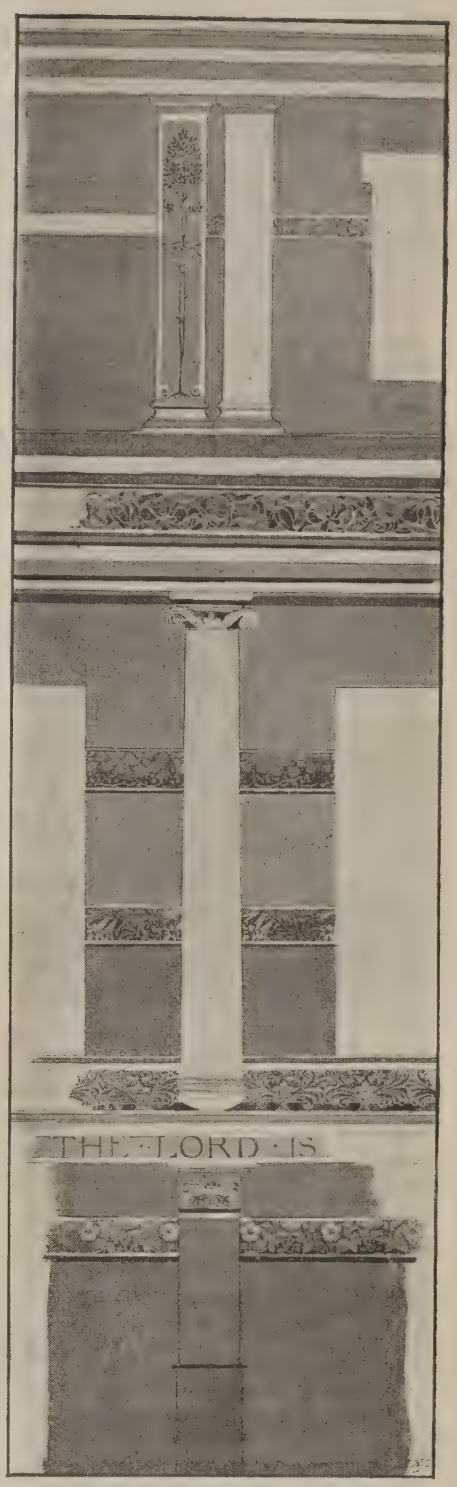
In offering the foregoing criticisms of the work it must not be presumed that the architect is at fault; rather must it be concluded that it is the restrictions which have been imposed upon him, many needlessly, to meet the views of the low-church congregation that have been incompatible with a perfect result. It is to be hoped that opportunity will be given him to effect the alterations which have been suggested. There are also several other changes that require to be made, chief among which is that the harsh gilded organ-pipes require to be toned down, and the organ case remodelled. The tablets on the east wall and another on a pier on the south side are most staring and should be removed, barring as they do any reasonable architectural treatment. The east wall is somewhat bare and a marginal line might have been marked below the chancel arch, but the tablets forbid the use of panels, the most obvious treatment. The old eagle lectern is a bad piece of work and should be rejected, but even a new one should be placed to one side, not centered to attract attention. The external doors are at present grained and varnished, and should be cleaned down and the wood left bare.

Mr. Ryan-Tenison has been particularly fortunate in obtaining the services of Mr. H. J. Pullen, of Brixton, as the contractor for the decoration and exterior work, for he has entered into the spirit of the work, taking personal charge of it. The workmen themselves appear to have made every effort. The following firms have carried out the other work:—Mr. Nathaniel Hitch, of 60 Harleyford Road, Vauxhall, the choir stalls, pulpit and sanctuary, and reframing of the altar in oak, and the wood carving; the Educational Supply Association, the nave seating and choir screens; the Italian Tile Company, the mosaic; Mr. A. Sclater, of 182 Oxford Street, W., the electric-lighting; and Messrs. Colbourne and Company, of Regent Street, W., all the hangings. The total outlay has been about £2,300, of this sum £850 being spent on the decoration.

THE ROOFING OF FARM BUILDINGS.*

BY ARTHUR T. WALMISLEY, M.INST.C.E.

THE paper does not pretend to arrive at any definite conclusions so far as the arrangement of farm buildings is concerned, but to touch upon a few considerations of details of structures. Farming practice differs so much that buildings which would be really needed in one district or upon an individual farm might be entirely out of place in another. Farmyard buildings are indispensable aids to farming practice, but in the midst of the present financial difficulties which embarrass agricultural interests, it is questionable how far the erection of very substantial farm buildings is now justified, as it is impossible to foresee what changes of occupation may take place in the future, which would render them more or less useless. Elaborate and expensive structures do not add, except in a minor degree, to the actual productive capacity of a farm. As regards implements, arable farms of a given acreage require more storage for implements than pastoral farms of the same extent.



Arrangement of Farm Buildings.

The design or shape of any building or structure for farm requirements may assume almost any form, depending not only upon the stability of the structure, but mainly on its situation and requirements, so that very little of a general nature can be said on this point. Many farmers advocate an open yard with sheds round it for storing cattle, as they consider that although there is a small waste in the manure, the cattle thrive better and are more healthy when they are turned out in the open as much as possible. Other more up-to-date farmers insist that the animals kept under cover, free from draught, and in a shed amply ventilated and built over a non-absorbent floor, are fatted quicker and at less cost than those exposed to weather. The manure made is also of greater value, as it is not exposed to the rain, which washes a large proportion of the valuable manurial constituents away. In open yards a suitable covering for a manure pit would consist of a rectangular enclosure surrounded by a wall 3 ft. or 4 ft. high (except in the centre at one end) and surmounted by a painted corrugated-iron roof, supported on H-section stanchions standing 10 ft. high from ground to eaves, so as to leave the upper portions of the ends and sides over this wall open; and provided with all necessary wrought-iron tie-rods, gutters, down-pipes, and fastenings. Exclusive of foundations and brickwork, the price, delivered ready for erection, is about 1*s.* 5*d.* per foot super. of area covered. The

Most Suitable Materials

for farm buildings depend upon local circumstances, but too much stress can scarcely be laid upon the proper location of manure pits and also upon the efficient drainage arrangements of all sheds. It is of primary importance to ascertain the various materials most accessible and the best that can be obtained in the district of the proposed structures, whether bricks, stone, cement, slates, tiles, timber, concrete, or iron, having regard also to the distance and convenience of carriage and the selection of the time most agreeable to the tenant, if, as is generally the case, he is to do the transport. Where bricks are reasonable in price and of near carriage, 9-in. brick walls upon proper footings, with piers 14in. wide under the principals, are well adapted for single-storey buildings. Concrete walls are very suitable in some parts, care being taken that the gravel or sand mixed with the cement is free from loam or clayey material. In a stone country a good rough rubble wall with drafted stone quoins, if the stone can be easily dressed, or otherwise with brick quoins, may be recom-

* A paper read before the Surveyors' Institution on November 26th, 1900.

FIRST SKETCH DESIGN FOR DECORATION OF ONE BAY OF NAVE, ST. JAMES'S CHURCH, BERMONDSEY.

mended, or where neither suitable stone nor brick are procurable, concrete may be used, either placed *in situ* in a plastic condition between timber sheeting and subsequently rendered in cement for sake of appearance upon the removal of the boards, or the concrete may be cast in blocks and these blocks built up like ashlar. For floors of any outbuilding concrete is more suitable than flagstone, as joints in flags frequently become washed out. Flagstones crack, and the cavities so formed become depositories for filth which no broom can clear.

Weather-Boarded Buildings

well tarred, upon brick bases, carried about 2ft. above the ground, are inexpensive in some places, and make satisfactory enclosures. (A sketch was shown of an outside covering resting upon four courses of brickwork, namely, a bottom course of 18in. width, the next course 14in. wide, both below the ground level, and a double course of 9-in. work above the ground level.)

In the case of a corrugated iron covering at the sides of the building, a galvanised iron flashing-piece is indicated to be fixed around the bottom timber plate, which flashing runs up about 2in. behind the iron sheets and returns over the top 9-in. brick course. A damp course can also be added by a layer of felt placed between the timber plate and brickwork below the floor level. Air-bricks can also be built at suitable intervals in the upper portion of the footings. A cheaper plan is to carry the building upon iron base pillars properly bedded, placed at 9ft. centres, and to omit the brickwork footings. By carrying these pillars up to a height clear of the ground a store can be built with a strong floor, vermin-proof. The price for a shed 25ft. by 15ft., suitable for a grain store, 8ft. to eaves and 12ft. to apex of roof, constructed on vermin-proof pillars, would be about 2s. 6d. per square foot of area covered.

Corrugated Iron Structures.

For corrugated iron work, self-supporting structures are, for the sake of economy, introduced. Trusses are dispensed with in curved roofs up to 30ft. span, the sheets alone with light bracing being sufficient. Its form gives it strength, and allows it to be fixed in a minimum time. Up to 20ft. span a single tie-rod, slung up at the centre, is generally employed, the sheets being curved to the required radius or maintained in position simply by tie and king rods spaced about 10ft. apart. In spans of 20 to 24ft. the single vertical central rod is removed and angle-iron struts with their ends bent round for connection are substituted. Comparatively heavier gauge sheets are introduced, and wall plates added along the eaves to carry the sheets. In spans of 24 to 30ft. the vertical central sling rod is added, thus forming a kind of halfway design between an ordinary principal roof and the curved self-supporting roof described above. Above this span principals and purlin bars need to be introduced so as to form a complete framework on which to secure the sheets. A curved roof of timber trusses for 50ft. span can be easily erected on the following lines:—Rise, 7ft.; depth of truss at centre, 5ft.; curved roof boarding, 36ft. 6½in. radius; radius of curve to tie-beam, 46ft. 10in.; rafter of tie-beam, composed of battens 7in. by 1¼in. and 6ft. long, fixed side by side, but joints made by two battens occurring in the centre of the adjoining batten; diagonal bracing, 2½in. by 1¼in., with packing pieces at intersections; two vertical struts, spaced equidistant, composed of 5in. by ¾in. battens; purlins, 3in. by 2in., and 3ft. apart (centres); roof boarding, ⅝in. thick; V gutter, 9in. by 9in. by 1in.; wall plate, 9in. by 3in.; principals at 7ft. 6in. centres, supported on wood standards with intermediate bracing.

The Cheapest Shed

that can be erected consists of timber framing to both the sides and ends carrying a self-supporting covering. Where timber rafters are introduced, with longitudinal battens fairly close together from rafter to rafter, the usual bolt connections in the side laps are frequently dispensed with, the corrugated iron as a weather covering being simply nailed to the battens and a ridge capping added. The cost of the necessary timber framing for such roofs, with rafters 5in. by 3in. having collar braces and spaced 2ft. 6in. apart, with wall plates 4½in. by 4½in., the battens being 3in. by 1½in., would be about 6d. per square foot of area covered.

A comparison between a slated and a zinc roof and a corrugated iron self-supporting roof, each covering an area of 100ft. by 25ft., would be—the slate roof costing about 1s. 1d., the zinc roof 10½d., and the corrugated iron roof 7¼d. per square foot of area covered.

To cover an area of 100ft. by 25ft. with a slate roof provided with principals and collars 9in. by 2½in., rafters 4½in. by 2½in., purlins 9in. by 3in., ridge 12in. by 2in., and plates 4½in. by 4½in., would cost as follows (fixed complete):—

	£	s.	d.
386ft. cube fir in plates, rafters, &c. @ 3s.	57	18	0
3,000 sq. ft. best Bangor slating @ 31s. 6d.	47	5	0
3,000 sq. ft. rough boarding @ 14s.	21	0	0
100ft. rim slate ridge roll @ 1s.	5	0	0
Lead flashing (5lbs.), 2c., 3q., 21bs. @ 24s.	3	6	6
Iron bolts, &c.	1	5	0
	£135	14	6

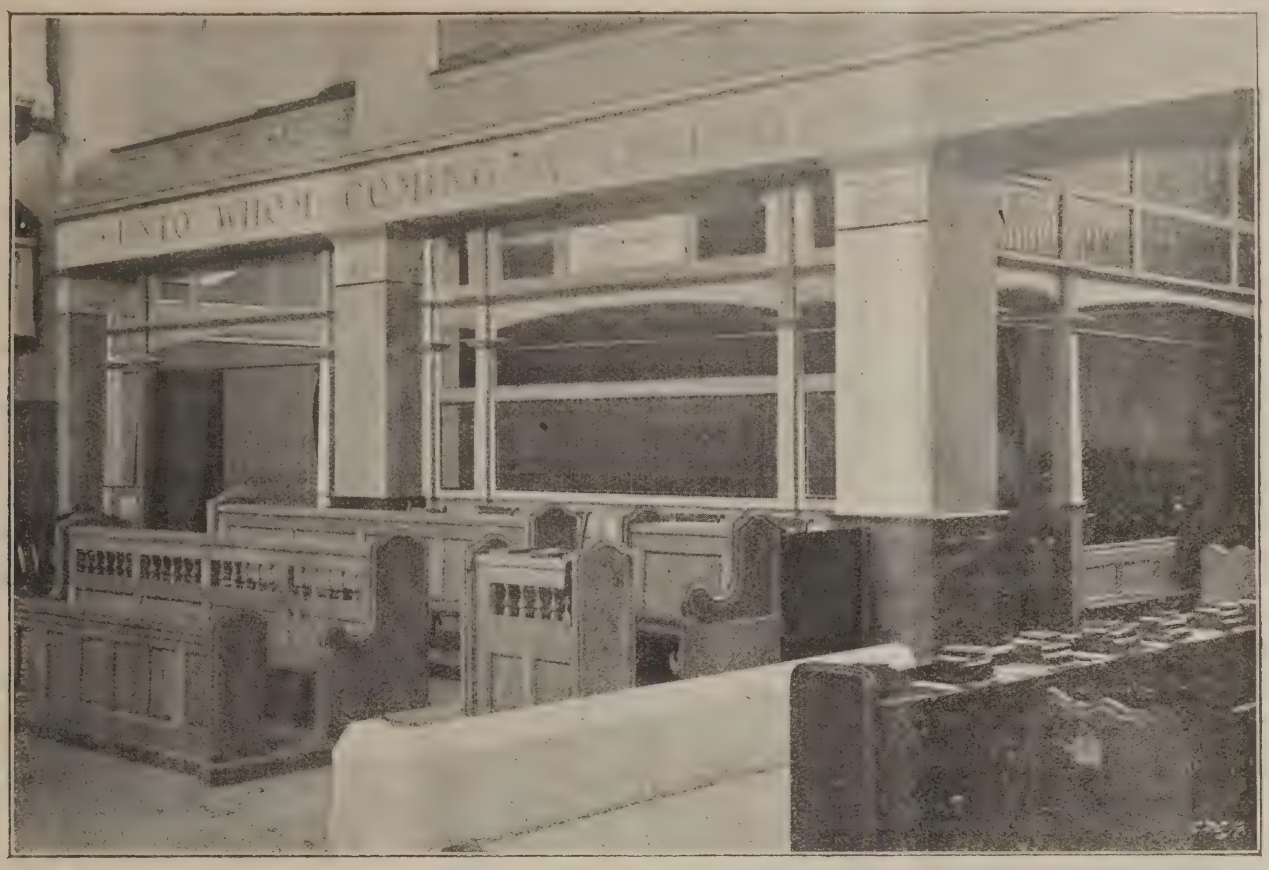
or 1·08s. per sq. ft.

To cover the same area with a zinc roof provided with principals and collars 7in. by 2in., rolls for zinc 3in. by 1½in., purlins 6in. by 2in., ridge 9in. by 2in., and plates 4in. by 3in., would cost as follows (fixed complete):—

	£	s.	d.
230ft. cube in plates, rafters, &c. @ 3s.	34	10	0
2,700ft. super. Italian zinc (Braby's) roofing, including ridging and flashing, No. 15 gauge @ 15s.	74	5	0
Iron bolts, &c.	1	5	0
	£110	0	0

or 0·88s. per sq ft.

These prices are of course subject to market fluctuations, but serve for purposes of comparison.



Where zinc is employed it is of great importance that it should be pure. Ordinary corrugated zinc cannot be recommended. For roofs of a permanent character either No. 14, No. 15 or No. 16 gauge should be used in the case of zinc, and either 18 B.W.G., 20 B.W.G., or 22 B.W.G. in the case of corrugated iron. Good iron well galvanised, or preferably ungalvanised and painted if near the sea, will last longer than thicker sheets of corrugated iron of inferior quality, and with regard to thin sheets of zinc or of iron it must be remembered that a surface crack allows the commencement of deterioration.

Lasting Qualities of Iron Buildings.

It is an erroneous idea that iron buildings do not last for any length of time. With proper treatment and periodical coats of paint, say every three years, these structures can be preserved for 30 to 40 years. Where exposed to acid or alkaline fumes, such as is occasionally

ST. JAMES'S CHURCH, BERMONDSEY: SOUTH FLANKING WALL OF SANCTUARY, SHOWING STENCILS AND INCANDESCENT LIGHTS IN GROOVE.

ST. JAMES'S CHURCH, BERMONDSEY: CHOIR STALLS, DWARF WALL AND SCREENS ON SOUTH SIDE.

the case in the immediate neighbourhood of covers to foal yards or dung steads, the galvanising may quickly deteriorate, and when once the galvanising is broken through, all the sheets quickly become perforated, whatever the thickness of gauge may be. A covering of copper sheets in such situations is preferable. The best protection under such circumstances for corrugated iron is to coat the sheets with good red lead paint or even a composition of pitch and tar a month or two after they have been erected, and to repeat this coating as may prove necessary—probably every three or five years. The reason for delaying the application of this covering until after the erection is completed is to allow such sheets to become tarnished upon the surface, since they will then allow the paint to adhere more firmly than when it is applied to a fresh metallic surface, and the whole area becomes covered without risk of further openings being made for connections.

When, for the sake of economy, galvanised sheets are used, it must be remembered that while the galvanising process protects the iron from corrosion it also tends to render the iron brittle. Notwithstanding this fact, the author is acquainted with a corrugated galvanised iron covering which stood over a large area of the Borough Market, Southwark, for thirty years, when it was found to be completely riddled in holes, and taken down as being likely to prove dangerous owing to the vibrations communicated from the railway viaducts which carried the roof framework. The value of the galvanised sheets employed for coverings mainly depends upon the quality of the iron. Although a certain excellence of quality is essential to allow the rolling of comparatively thin sheets which shall be able to endure the corrugation required without risk of damage, yet it will be found upon examination that large quantities of inferior sheets are sold in the market which have minute cracks or a blistered surface. Sheets of this character will not hold the spelter properly, or if ungalvanised and painted, the smallest flaw in the continuity of covering gives an entrance for the weather, with a serious result. Rust from the exposed spot spreads laterally under the covering and when the rust separates from the iron, the paint comes off with it. Charcoal sheets sold by manufacturers at extra prices for galvanising are not an ordinary article of commerce. The sheets sold by manufacturers at extra prices for galvanising and other purposes under the name of "charcoal sheets" are generally made of steel.

A Hay Shed.

(Reference was here made to a hay shed with a corrugated iron roof 20 ft. wide constructed in 15 ft. bays). The shed is 14 ft. high at the eaves, and the curved roof has a rise of 4 ft. 6 in. The intermediate framing of the roof is formed of angle-iron rafters with flat iron tie-bars. They are partly riveted together at the maker's yard and are provided with a necessary shoe and splicing plates. The roof is carried on H steel columns, spaced at 15ft. centres, and special attention needs to be paid to the connections between the column heads and the roof framing. This form of stanchion is the best to adopt, where the columns are liable to be knocked against by carts or the like. Where possible, they should be let in from 1 ft. to 2 ft. into solid concrete blocks bedded in the ground, and spur stones added. In the case under review the columns have angle bases riveted on to their feet, for anchorage into the concrete foundation. In each bay, between the heads of the columns, there is a light lattice girder formed of angle-iron eaves bar, and spandrel with flat iron bracings, all riveted together, including the necessary splicing plates on the columns. The end frames are formed of angle-iron rafters, tie-bar and uprights, with the necessary shoe and splicing plates, and have a stay of angle-iron from the tie-bar to the crown of the roof. The roof in this case is covered with Braby's No. 22 W. G. best "Empress" brand, galvanised corrugated sheets, laid with 6 in. end laps and one corrugation side lap, fixed to the eaves bar with clips and to the crown bar with hook bolts, and bolted to each other by means of sheet bolts, all provided with galvanised material and lead washers. Angle-iron crown purlins extend from end to end of the roof, secured to the crown of the gables by means of splicing plates; galvanised half-round wrought-iron eaves gutter is fixed along each side with gutter hooks spaced every 3ft.; and galvanised wrought-iron down-pipes secured to the stanchions by galvanised iron clips are added, but their ends are left free to avoid connections to the underground drains. The ends of the shed can be clad with vertical corrugated sheets similar to the roof. Gutters and down-pipes should always be of ample size to facilitate clearance, and the top of a down-pipe should be provided with guards to prevent choking by leaves and dirt. When not galvanised, they are usually formed in cast-iron, since this material, as a rule, will better resist corrosion because of the greater body of thickness in a casting compared with thin wrought-iron or steel gutters and down-pipes. An open shed as described above could be erected for about 1s. 5d. per square foot of ground covered. If side sheeting is necessary, the price to include covering the sides down to a depth of 4ft. below the eaves with its necessary framework would be an addition of about 2s. 3½d. per foot run of covering.

With hay and corn sheds, head room is a consideration; hence the adoption of trusses with a raised tie-beam. But in many cases they are braced and covered with corrugated iron, carried at the eaves on a wall plate which may be of timber or of iron. For hay sheds it is always advisable to have the framework entirely of iron or steel, as in case of fire the damage done will not be so considerable as if part of the framing were of timber.

(Attention was here drawn to a simple arrangement for a coach-house and stable, 40ft. by 13ft., costing £95 fixed, or 3s. 8d per square foot of ground space.)

Lighting and Ventilation of Sheds.

Where possible, all lighting to a shed should be obtained from the sides or ends of the building enclosed at the sides and ends, because roof lights, besides being somewhat costly, are apt to leak during wet and stormy weather.

Ventilation may generally be arranged mainly under the level of the eaves, only a limited amount (if any) being required in the roof itself. Nothing can be worse for a stock-yard than a draught, especially a cross draught induced by too large openings in the ends and at the sides of a building. Ventilation is needed above and not across a yard. The usual louvre ventilators seen in the roofs of railway stations admit snow in winter. By raising the covering at its junction over an intermediate purlin in wide sheds and adding a pile plate or ridge piece above an upper purlin, effective ventilation may be evenly distributed along the whole length of the roof in lieu of the ordinary louvre-board arrangement. A system which can be

recommended in truss roofs consists of a ventilating ridge provided by the introduction of 4in. by 2 in. woodwork, perforated and running the whole length of the ridge both sides; but there are very few roofs of farm buildings that provide a double roof to permit this means of ventilation, and with self-supporting roofs it would be only practical and safe to provide a number of small ventilators at prescribed intervals along the ridge. Of course, with ridged framed roofs any amount of ridge ventilation can be given, either continuously, or by means of small independent ventilators at intervals.

Continued progress is being made in the application of iron and steel to building purposes, and the demand for structures of these materials increases. This is not surprising when we consider the advantages which iron and steel possess in allowing a building to be sent to the place of erection complete and ready for fixing, in the small extent of ground surface taken up by walls and partitions, in their imperviousness to moisture, and the practicability of rendering a building fire-resisting though not fireproof, and also in the ease with which a complete and thorough ventilation of a building can be arranged, and in the facility of removal and comparatively small cost of reconstruction in any other part of the farm.

Wind Pressure.

Strong winds or gales should be specially taken into account in all buildings standing exposed to their action, and extra precautions adopted to prevent the force of such gales getting under the roof, since the majority of accidents to light self-supporting roofs are due to the lifting tendency of wind having free play underneath them, without being able to escape. In designing roofs it is sufficient for ordinary purposes to assume that there may be a lateral wind-pressure of 28 lbs. per square foot and a weight of snow equal to 5 lbs. per square foot. These, added to the weight of the structure, give the total load to be sustained, and the working strain upon the material employed under such circumstances should be about one-fourth, and should never exceed one-third of the calculated breaking strain. Wrought iron of 20 to 22 tons per square inch ultimate breaking strain is a fair assumption. To specify a higher unit breaking strain is to invite a manufacturer to deliver mild steel.

Rectangular buildings may be covered with roofs having gabled ends, or the ends may be hipped. The hipped portion is, however, more expensive than the ordinary parts of a roof, the framework requiring more labour, and the covering is greatly cut to waste. As an approximate rule, one-third should be added to the general price per square of 100 superficial feet for that portion of the area which is covered by the hip. Against this extra, however, we have to consider the saving effected in the material that would be needed if gables were used. By simplicity of construction expense may be saved. Smith's work should be reduced to a minimum, and welding both at the joints and other parts avoided as much as possible. So far as the site will permit, a roof should be arranged to contain a repetition of parts, as upon the extent to which this is effected the cost so much depends. A building divided into equal spaces, and in which the principals occur at regular intervals, is the cheapest that can be adopted.

Cheap Construction.

It is evident that expense may be saved by preserving as far as possible all existing buildings and making use of the existing walls, also by roofing in considerable areas in a block so as to subdivide the interior by light and inexpensive partitions with a view to facilitate subsequent alterations and save the cost of numerous outside walls. The use of expanded metal in concrete may be advantageously introduced in wide spans of roofing or partition. The continuity of buildings affords opportunities for an advantageous disposition of material in unbraced structures, as it admits of introducing the nave and transept principle by placing the direction of one portion of the covering at right angles to the remainder.

While the limited amount of framework needed for corrugated iron recommends it for rapidity of erection at moderate cost, it is sometimes objected to as a covering because it does not moderate the extremes of heat and cold, and the interior of such buildings is consequently easily affected by changes of temperature. A double roof is undoubtedly the best means of retaining warmth and of excluding external heat, but in ordinary sheds an inner lining of boarding, leaving an air space of about 9in., would be too expensive, so the difficulty has been surmounted by running some light wires parallel with the purlins of a roof, and about 12in. apart, upon which a thin layer of straw is laid. The comfort of a thatched roof is to some extent attained in this way.

Thatched and Tiled Roofs.

Thatching possesses some advantages over other methods. It is light, impervious to moisture, and of good weathering quality when skilfully laid. Wheat straw is the best to employ, being a good non-conductor and more durable than oat straw. For coverings in isolated positions it is very suitable, but it needs to be particularly secured at the eaves to avoid lifting under the influence of high winds. In some farms galvanised rick-covers are used, fastened by strand wire looped both ends in an approved manner, and are advantageous.

Tile roofs are seldom watertight. Pantiles are common and cheap. Plain tiles are expensive. They are smaller than pantiles, but requiring more lap they are heavier per square. They can be laid to any slope from 25deg. to 60deg. Slates need an angle of about 2 to 1 or 25½deg. to 30deg., but zinc, lead, and corrugated iron can be laid at a slope of 4 deg. Pantiles are mostly used for barns and sheds. They need strong roof timbers. Their size is about 13½in. by 9½in. by ½in., weighing 5½lbs. each. Plain tiles are 10½in. by 6½in. by ½in., weighing 2½lbs. each, and 11in. by 7in. by ⅝in., weighing about 3lbs. each. A square of roofing requires 800 plain tiles laid to a 3-in. gauge, 700 tiles to a 3½-in. gauge, and 600 to a 4-in. gauge. They need to be fastened with a galvanised iron nail for security to fir laths attached to rafters, no boarding being necessary. Pantiles hold the moisture a long time and are inferior to plain tiles.

Other Forms of Roofing.

Roofs covered with felt should have a slope of at least 1 in 5, indeed 1 in 2 would not be too much. Croggon's asphalt roofing felt is specially coated with an admixture of bitumen, and is considered impervious to rain, snow, or frost. It is sold at 1d. per square foot, subject to discount.

Willesden paper has frequently been employed for roofing purposes. The 4-ply at 9d. per yard run, 19 in. wide, sold also at 2s. 6d. per yard run, 60in. wide, can be laid directly on rafters or partition studding without boards. In the case of roofs for exterior service it is held in position by outside battens 2½in. by 1in. firmly nailed through the overlapping roofing. To suit the width of the paper, rafters 19in. from centre to centre are required. At the eaves it is usually turned round a feather-edged board for security. It is found to be durable, but for permanent work should be painted every three years. In exposed situations it needs protection from wilful destruction, as it is easily damaged by mischievous boys throwing stones. When properly fixed at the outset, with ample overlap at the ends, Willesden paper proves itself capable of resisting gales and of withstanding the weather, but its sagging in wet weather is unsightly and inconvenient. It answers very well as a covering to keep dry, but is too free a conductor of heat and cold for covering cattle sheds. It, however, makes a first-class underslating.

A substantial form of continuous timber roofing consists of timber verticals 7ft. 1½in. apart longitudinally and 18ft. span, weather-boarded to be covered with zinc, corrugated iron, felt or other covering. Windows, doors and sideboarding can be fixed as required, and the whole forms a class of covering suitable for a sheltered position that can be easily erected.

GEORGIAN ARCHITECTURE IN DUBLIN.

THIS was the title of a paper recently read before the Architectural Association of Ireland by Mr. T. E. Hudman. It dealt chiefly with the period between 1714 and 1830, which, the lecturer said, may be called the "Golden Age" of Dublin, as far as its buildings are concerned. Previous to this many of its men had world-wide reputations, but, architecturally speaking, with the exception of Christchurch and St. Patrick's Cathedrals, Dublin was practically a dead city. During the reign of the Georges the population of Dublin increased from 8,000 to 169,500, and the city expanded from what was little better than a small mediæval town, with narrow streets and a congested population, into a metropolis with wide streets and many noble buildings, mainly due to the efforts of "The Wide Street Commission," appointed by Act of Parliament in 1757. This Commission, composed of men of parts and enlightened views, devoted their energies to making what was really a new city, and their first instructions were "to open an avenue from his Majesty's Royal Palace to Essex Bridge." Subsequent acts empowered them to carry out other great public works, and in course of time the fine squares and streets both on the north and south sides of the Liffey came into existence. History repeats itself, and these schemes of improvement were not carried through without opposition, and it became necessary to employ an army of men to strip the roofs from the houses in some localities before the inhabitants could be persuaded to give up possession. Many of the oldest houses, now rapidly disappearing, are undoubtedly of Dutch origin, but the buildings of the later period, both public and private—as, for example, the Custom House, Trinity College, the Bank of Ireland, the Four Courts, the City Hall, Rotunda, the King's Inns, St. George's Church, Aldborough House, Drogheda House, Charlemont House, Belvidere House, Blessington House, and numerous smaller houses, designed by such master hands as Sir William Chambers, Gandon, Cassels, Thomas Cooley, Sproule, and Eason, &c.—are still with us, and many of them have been well cared for. The striking feature of Dublin is its wide line of streets and squares, and the effect of its public buildings so judiciously placed—the line from College Green to Rutland Square would be hard to beat, not to mention Merrion Square, Fitzwilliam Square and St. Stephen's Green, and the surrounding network of streets. The line of quays starting from the Custom House and finishing with the Phœnix Park was a magnificent conception. Unfortunately the controlling influence over some of the buildings *en route* appears to have relaxed, and the decadent period set in before the scheme was completed, but even now under certain conditions of sky and atmosphere the view looking westward from Carlisle Bridge is superb, both for colour and architectural effect.

Current Periodicals.

The Antiquary.—In the December number an illustration is given of Hurstmonceaux Castle, in the county of Sussex, two leagues from the spot where William the Conqueror landed. It was built by Sir Roger de Fienes in the fifteenth century at a cost of £3,800, Flemish workmen being employed.

The Art Journal.—To Part VIII. of "The Paris Exhibition" (special series of this journal) Mr. Claude Phillips contributes an article on the Spanish Pavilion, which was considered by some to be the most imaginative and charming piece of architecture in the Exhibition. The remainder of the number and the frontispiece are devoted to reproductions of scenes in the "Village Suisse" and to detailed descriptions of works in bronze, glass, wood, tin, and porcelain. There are altogether 77 illustrations in the number.

Carpentry and Building (New York).—It seems probable that an Architects' Registration Bill will be introduced during the coming session of the Legislature of New York State. The proposal is being fostered by the Architectural League, and is being supported by leading architects. There appears to be the same complaint across the water, as here, about the non-recognition of architects as professional men, and about the impostors who practise. Among the articles in the December issue of this publication is an interesting one on leaded-glass work and another on caissons for foundations.

The British Clayworker for November includes articles on the brick-earth of the Bicester district, the South Staffordshire Brickmasters' Association, brick drying, and the setting and burning of a Hoffmann kiln. A reprint from a local paper states that the Birmingham brick manufacturing industry is passing through a period of unprecedented depression which almost threatens its extinction; this is alleged to be due to ruinous competition of other brick manufacturers, the building trade slump, the excessive cost of fuel, and the unfair system of rating the manufactories.

R.I.B.A. Journal.—In the issue for November 10th it is stated that instead of the paper on "The Work of Sir Charles Barry," announced on the sessional programme to be read before the Institute on April 22nd next, one on "The Work of Inigo Jones" will be given. The issue for November 24th contains Professor Lanciani's paper on the Forum excavations (with illustrations). Mr. Arthur Cates, who has already done so much in the matter of architectural education, gives full particulars of the Cornell University in America, where the architectural curriculum has recently been reorganised in order that so much of the Beaux-Arts ideal as appeared suitable and possible might be incorporated.

Pall Mall Magazine.—Vol. XXII. comes to an end with the December number, as do also Mr. G. S. Street's notes "From a London Attic." An article on "Royal Tapestry at Windsor" is accompanied by some excellent illustrations of the magnificent Gobelins. The article is a most interesting one, and concludes with the remarks that at the Gobelins factory a weaver now possesses a choice of more than 14,000 tones of colour, and can only make about 9 sq. yds. of tapestry in a year, the retail value of which is about £350. The looms and tools used are of the simplest description, but it takes at least fifteen years to produce a weaver possessing an artist's eye and a workman's hand. In the January number of this magazine there will be an illustrated article on the great French sculptor, Rodin.

The Genealogical Magazine.—At Hexham, about the year 660, Wilfrid built his church, of which the crypt is now the sole remaining portion. In 1881 certain excavations were made beneath the floor of the slype (or long porch) near the entrance door, and an interesting memorial tablet was unearthed. An illustration of it is given in the December issue of this magazine. The slab represents a Roman standard-bearer carrying the "Eagles," a nude Ancient Briton crouching beneath his horse. Antiquaries place its date at about the second century, and a classical scholar has translated the inscription as follows:—"To the Gods, the Shades. Flavinus, knight of the Petriana Cavalry, standard of the squadron of Candidus, aged 25. Time of service, 7 years. (Here lies.)"

Magazine of Art.—The Chinese have a god of architecture who is worshipped when a new house is built, but he is ignored until the time comes for the builders to commence work. The Rev. W. Hopkyn Rees says, in the December issue of this magazine, that there is no Society to safeguard the interests of architects in China, as professional architects do not exist; each man settles his plan *verbally* with the builder. There is little fear of dissatisfaction, however, as no break in the "style" has occurred for centuries. Comparatively few of the buildings have any architectural beauty. Kiln-made bricks cost 10s. a thousand, sun-dried bricks about 2s. 6d. a thousand, while the windows of the houses are made of wooden gratings covered with oiled paper. Some of the pagodas (of which there must be at least two thousand in the empire) are elegant—like that, for example, in the Summer Palace at Pekin—and it is remarkable how long they remain standing. There is one not far from Shanghai, 170ft. high, which was built in the twelfth century. The White Pagoda in Peking was built in 1100 A.D. But looked at by Western eyes Chinese architecture is a poor thing: it is not comparable with the great Indian buildings.

The Engineering Times.—Writing in the November number on the subject of electric street traction in England, Mr. J. Clifton Robinson plainly shows that he has little sympathy for æsthetic considerations in connection with electrical tramways. He assures us that "many an English street has been vastly improved by the artistic street standards which now ornament its public ways"—perhaps those which have been erected on the Uxbridge Road by the London United Tramways (of which Mr. Robinson is managing director and engineer). There can be no doubt that as regards simplicity in construction and economy in working the overhead system is far ahead of the conduit system, but it is sadly deficient in appearance. There is a great dearth of engineers with a feeling for fitness and beauty, and consequently we have bridges and street standards which are spoiled by their vapid ornamentation. An article on "Machine-Driving by Separate Motors" deals with the increasing application of electric motors for driving individual machines, and the writer asserts "that in a few years' time the lathe, drilling machine, printing press, and such machinery will be very generally driven in this country by independent motors."

The Architectural Record (New York).—With the October number this interesting magazine begins its tenth year. We are all familiar with the famous Farnese Palace, but hidden away in the fair Ciminian hill country is a gem of the Renaissance which is unknown and unvisited by the omnipresent traveller. This is the Villa Farnese at Caprarola, the splendid work of Vignola. It is pentagonal on plan (making it almost unique among Italy's Renaissance palaces), and on entering the vast stone hall one feels as if he were inside the palace of the "Sleeping Beauty," leading an enchanted life behind these sixteenth-century portals which shut out the outer world so completely. The building, which is now inhabited for the greater part of the year by a family of Viterbese nobles, has some fine architectural features—the circular courtyard, the "Scala Regia," and the many beautiful halls, such as the "Hall of the Farnese," the "Council Chamber," the "Hall of the Aurora," the "Chamber of Judges," the "Chamber of Dreams," the "Chamber of Angels"; and in the garden stands Michael Angelo's "Seahorse Fountain," an additional beauty to the building. In the issue under review Professor Hamlin deals very ably with modern French architecture. The Roman revival in France, which began with the Pantheon and culminated under the First Empire in the Madeleine and the Bourse at Paris and the Grand Theatre at Bordeaux, produced a number of stately façades but it effected little change in the interior design and decoration of buildings. It was Duc, Duban, and Labrouste who were the pioneers of the new movement which resulted in a thorough architectural awakening under Napoleon III. and the *coup d'état* of December, 1852. The Neo-Grec movement led above all to a refinement in profiles and mouldings, which has ever since—or until recent years—been a marked characteristic of French work. The October number also contains an article on M. Emile Wauters, the Belgian painter of architecture, and on the Tiffany House, New York; the latter was entirely designed by Mr. Louis C. Tiffany, and, though possessing the merit of originality, shows in many parts a straining after effect—the superabundance of small objects, such as vases and plates, also detracts greatly from the appearance of the rooms.

Scientific American (Building Edition).—Illustrations are given in the November number of the Castle of Lauenstein, situated in one of the most romantic portions of the Thuringian Forest. The original castle was built in the tenth century, but the present building is a restoration. Other illustrations show the new Public Library at Providence, R.I. (Stone, Carpenter and Willson, architects). This is a good example of a Renaissance building treated with restraint. It has fine proportions and good detail, but is marred by a length of railing at the eaves.

Stone (New York).—A writer in the October number deals with the causes of failure in connection with new quarries. A man during an idle wandering discovers a deposit of stone, dresses it, and finds it is undeniably beautiful. Then he satisfies himself that there is enough of it, acquires the land, and begins working. The stone is all right, but the public does not want it; and so ends this cart-before-the-horse method of introducing a new stone. Another writer in this issue suggests that the time is ripe for the introduction of American paving stone in this country, while a paper is given on quarrying by the helicoidal wire, by which cuts about 41ft. long and of equal depth can be made in rocks of slight hardness. The helicoidal wire is a wire-cord formed of three hard steel wires twisted together with a very slow pitch.

Architecture (New York).—The November issue of this publication is less interesting than usual. Among the illustrations is one of the new town hall at Lynton (Read and MacDonald, architects). It is stated that an exhibition will be held at Washington, during the annual convention of the American Institute of Architects, of the drawings for Government work made by private practitioners under the authority of the Tarnsey Act, the competitive drawings for the University of California, and the American architectural exhibit at the Paris Exposition. This will be the first attempt in America where a special effort has been made to publicly exhibit drawings of Government work done outside the sacred precincts of the Supervising Architect's office. Architectural clubs are rapidly increasing in number in the United States.

The American Architect.—A protest is made in the issue for November 3rd against the present scheme of alteration to the White House at Washington. It is proposed to build two wings at right angles to the present structure, connected by what are called "curved corridors"; these are not only curved, but splayed and bent in the most extraordinary manner, and our contemporary states that the design is artistically ridiculous. Mr. Gilbert's statue of Lord Pembroke, recently erected at Wilton, near Salisbury, is truly set on a stupid pedestal, designed by "the amateur artists of the family," who conceived the idea of a home-made design. Such an act is grossly unfair to the sculptor. The plates with this number include one of the Walker Art Gallery, Bowdoin College, Brunswick, Me. (McKim, Mead and White, architects), and three of lunette decorations by Abbott H. Thayer, Kenyon Cox, and Elihu Vedder. This is a fine Renaissance building, showing much restraint in design. The issue for November 10th includes plates of Mr. John Tweed's statue of Mr. Cecil Rhodes and two of the panels at the base.

Masters and Men.

The Strike of Plumbers at Stockton has ended, the men being given an advance of ¼d. per hour, with the promise of another ¼d.

The Sutton Coldfield Master Builders' Association held its annual meeting and dinner last week. The president, Mr. J. R. Jones, occupied the chair.

The Penrhyn Quarries will be reopened to-day, and the old hands are invited by Mr. Young, the chief manager, to make applications afresh for their ordinary monthly bargains.

The Belfast Carpenters' and Joiners' Dispute.—Last Tuesday the strike entered on its thirty-first week, and the prospects of a settlement seem further off to-day than at the commencement of the dispute.

The Bradford Building Trade.—There is trouble looming ahead in connection with the Bradford building trade, and it is probable that a strike will take place next May. On account of depression the local branch of the Master Joiners' Association have asked the men to accept a reduction of one penny per hour. The necessary six months' notices of reduction has been given, and they will expire next May. The men have replied with a demand for an increase of one penny per hour, and their notices will expire in May. Last year there was a local strike, and the men were eventually given a half-penny per hour increase, making the wages 9d. per hour. The masters now want to reduce them to 8d., and the men want 10d.

The Leeds Masons.—Considerable unrest exists in the building trade in Leeds, but for the present no developments of any important nature are likely to take place. In Leeds the masons have made application for an advance of ½d. per hour, bringing their wages up to 9½d.; but as, under the arrangement between the men's Union and the Master Builders' Association, a six months' notice has to be given of any change, nothing is likely to be done in the matter for some time, the demand only having been made at the beginning of the present month. As the building trade in Leeds is in a flourishing condition at present, and as the wages paid to the masons are substantially less than those paid in many other towns, it is probable that the employers will grant the advance asked for. A similar advance was recently granted to the bricklayers.

Newcastle Building Trade Dispute.—A meeting of the Northern Counties Federation of Master Builders and Bricklayers was held in Newcastle recently to consider the men's demand for an advance in wages of 1d. an hour from 10½d. The employers insisted on referring the claim to arbitration, or giving a guarantee that wages should be unaltered for the next two years. Owing to the decision of the men in Newcastle and Gateshead to reject the proposal of the employers, the practical lock-out of all bricklayers in the Northern Counties began to take effect from midday on Saturday week. The Northern Counties embrace Northumberland, Durham, part of Cumberland, and part of Yorkshire, including the important town of Leeds. The total number affected will be several thousands, and this will be greatly increased in the course of a very short time, owing to other trades engaged in building operations being brought to a standstill by the cessation of work of the bricklayers. The outlook during the forthcoming winter is of a very gloomy character.

The Architectural Association of Ireland.—The first of the series of technical demonstrations inaugurated by this society was held last week at Messrs. H. and J. Martin's yard, Grand Canal Street. There was a large attendance, over forty members being present, who listened with much interest to Mr. J. Martin's remarks upon bricks, sand, cements, mortars, &c. Many new members are joining the Association in order to avail themselves of these demonstrations, which are announced in our "Coming Events" column.

Engineering Notes.

New Bridge at Runcorn.—The Runcorn Urban District Council have decided to invest £10,000 in the Widnes and Runcorn Transporter Bridge Company. The bridge is estimated to cost £100,000.

The Cottage Hospital, Hinckley, is being warmed and ventilated by means of Shorland's patent Manchester stoves, with descending smoke flues, supplied by Messrs. E. H. Shorland and Brother, of Manchester.

An Extensive Scheme.—Application is to be made to Parliament for leave to construct a very extensive system of electric tramways in Surrey and Middlesex. There are in all twenty separate tramways set out in the scheme.

New Landing-place at Pembroke Dock.—The War Department has decided to construct a new landing-place between the Hobbs' Point and railway piers at Pembroke Dock, and an initial expenditure of £10,000 will be provided for in the Army Estimates for the financial year 1901-1902.

Folkestone Tramways.—By a poll declared last week the Folkestone owners and ratepayers have reversed the decision of a Common Hall to authorise the Corporation to proceed for a Bill sanctioning an expenditure of £100,000 on municipal tramways. The Corporation will now probably promote a smaller scheme, and apply for a provisional order.

Smoke Combustion.—The Western Smoke Consumer and Fuel Economiser, Limited, of 8 Shute End, Wokingham, manufacture a fire-bridge for boilers which forms the back of the furnace as a hollow chamber, into which cold air is admitted, heated, and passed into the fire. It is claimed that there is an economy in fuel, that the flues are kept free from soot, and that no tapping or drilling of the boiler is required when fixing the device in position.

Vauxhall Bridge.—The new Vauxhall bridge is making progress; but the completion of the first contract, which is to bring the structure up to the water level, is not yet within measurable distance. One of the old piers has been cleared out of the way, but there are three others yet to be attacked. The abutment on the north side has made considerable advance, and the Lambeth abutment is well in hand, the difficulties with the sewers, which constituted a very awkward part of the work, having been effectually disposed of. When plans were first made, it was calculated that the temporary bridge which it was proposed to put up would have to serve for about ten years, during which time it would take first of all the traffic of old Vauxhall bridge, and after that it would serve similarly for the old suspension bridge at Lambeth. According to the present rate of progress, it looks as though Vauxhall will take the whole ten years.

Electric Tramways in South Lancashire.—The South Lancashire Tramways Act, passed last session, authorised the construction of an extensive system of electric tramways for the transport of passengers and goods in the populous district lying between Manchester and Liverpool. The scheme, which is the largest ever embraced in a private Act, extends to 84 miles of tramway lines, all the principal towns of South Lancashire being touched en route. From Bolton there is a further project to be submitted to Parliament in the ensuing session for extending the system northwards to Darwen and thence to Blackburn; while on the southern side of the county there is a contemplated extension to Warrington by means of a line branching off from Earlestown.

Lambeth Bridge.—The Bridges Committee of the London County Council have determined to recommend the Council to undertake at the earliest period the rebuilding of Lambeth Bridge. In March 1887 attention was directed to the critical condition of the abutment anchorages of the bridge. Sir Benjamin Baker advised that, unless the authorities were prepared to accept the gravest responsibility, there was no alternative but to increase the stability of the bridge. Upon this advice certain repairs were effected. Iron gates have been provided at each extremity of the bridge to close it on emergency, and the Council has considered it necessary for it to be watched day and night. It is often necessary to close the bridge, and the Bridges Committee is of opinion that no main thoroughfare should be in such an unsatisfactory condition that it requires to be closed at short notice. When the suggested improvements at Millbank Street, Westminster, were under consideration, much discussion took place as to the necessity of rebuilding Lambeth Bridge, and an opinion was expressed that the bridge should be rebuilt at the earliest possible moment. These, among other considerations, have led the Committee to recommend the Council to rebuild. Four designs have been prepared—(1) a suspension bridge, (2) a braced-arched bridge, (3) a steel five-arched bridge, and (4) a granite-faced concrete five-arched bridge. The Committee recommend the Council to adopt No. 4. The chosen type is the same as that of the bridge now being erected at Vauxhall. The total approximate cost, including maintenance and painting when required, is £308,000. The clear span in the centre will be 158ft., and the headway given will be 20ft. above Trinity high-water mark.

The Widening of London Bridge.—Referring to the proposed widening of the footways of London Bridge from 9ft. to 14ft. at a cost of £100,000, Mr. Robert Greening suggests that before so large a sum of money is expended in affording merely a temporary relief to the pedestrian traffic, the question of the necessity of widening the roadway should also be taken into consideration. In his opinion the roadway ought to be made half as wide again, so as to allow six rows of vehicles to pass abreast. The most effectual method of relieving the congested traffic, short of building a new bridge, would be, he says, to bodily widen the entire bridge on its eastward side, to double its present width, and to pull down the dozen or so mean-looking shops and offices in King William Street on the same side, between Adelaide Place and Eastcheap. It may be mentioned in connection with the widening of London Bridge that there has long been a project of constructing a replica of Waterloo Bridge across the river near the eastern end of Somerset House. The widening of London Bridge, conditionally upon the consent of Parliament, was decided upon at a meeting of the Court of Common Council held last Thursday. We gave in our last issue a section showing in detail the construction to be adopted. This has been designed by Mr. Andrew Murray, F.R.I.B.A., surveyor to the Court of Common Council, Mr. E. Cruttwell, M.Inst.C.E., collaborating as engineer.

The Glasgow and West of Scotland Technical College Architectural Craftsmen's Society held a meeting on November 23rd, when a paper entitled, "The Duties of a Clerk of Works," was read by Mr. W. U. Muir. In the course of his remarks the lecturer strongly recommended the regular reporting to the architect each week on the progress of the work by means of written statements framed on lines such as: Number of men in respective trades employed each day, with number of hours of each; state of weather and amount of work accomplished each day; drawings received and drawings required. The taking of notes of extras or modifications on the work was also considered to be essential, these being of great assistance at completion in the checking of accounts, &c.

HOLBORN TO STRAND THOROUGHFARE: PLAN OF DESIGN NO. 29.

Builders' Notes.

The Newcastle, Gateshead and District Building Trades Exchange held its annual dinner last week. Mr. J. G. Walker, chairman, presided, and Mr. W. Lister Newcombe was in the vice-chair.

Messrs. Young and Company, stable and cow-house specialists, have removed their offices and showrooms from No. 12 Victoria Street to much more extensive premises at No. 161 Victoria Street, the same side as the Army and Navy Stores, and close to Victoria Station.

Unprotected Machinery.—Messrs. J. Garrett and Son, builders, Balham Hill, were fined £20 last week at the South-Western Police-Court for neglecting to fence a surface planing machine, owing to the absence of a guard from which a workman had had three of his fingers cut off.

Huts for Soldiers in South Africa.—Mr. George Jamieson, builder, Woodside, Aberdeen, is making steady progress in carrying out his contract for the provision of huts designed for the accommodation of the forces in South Africa. Eighteen of the huts were transferred to the War Office authorities for shipment on Novem- 30th. Each of the 18 huts contains accommodation for twelve men, and to each of the men separate apartments are assigned, these apartments, provided with door and window, being 10ft. long and 8ft. broad. The huts now being prepared by Mr. Jamieson are intended for officers' servants, and they have received the approval of the War Office officials.

Partnerships Dissolved.—The partnership heretofore subsisting between Messrs. Fred Briggs and Sutcliffe Ingham, carrying on business as builders and contractors, at Lidget Green, in the city of Bradford, under the style or firm of Briggs and Ingham, has been dissolved by mutual consent as and from November 8th, 1900. All debts due to and owing by the late firm will be received and paid by Messrs. Fred Briggs and Sutcliffe Ingham, or either of them.—The partnership heretofore subsisting between Messrs. Willian Wray and Michael O'Flynn carrying on business as builders and contractors, in the city of Bradford, under the style or firm of Samuel Wray and Co., has been dissolved by mutual consent as and from June 1st, 1900. All debts due to and owing by the late firm will be received and paid by Michael O'Flynn.

Enquiries Answered.

The services of a large staff of experts, including all those engaged on "Specification," are at the disposal of readers who require information on architectural, constructional, or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Design of Small Houses.

LONDON, S.W.—L. A. H. writes: "Kindly state in which numbers of your Journal a series of articles on small house design appeared."

A series of articles on the "Planning of Small Houses," by H. V. Lanchester, appeared in our issues for February 10th and 17th, March 10th, April 21st, May 19th, and June 23rd, 1897. A series on "Design and Detail of Domestic Building," by John E. Newberry, appeared in our issues for March 23rd, May 25th, and July 6th, 1898, and January 4th, 1899.

Supporting Stone Head.

QUESTIONER writes: "If a large opening is spanned by a stone head vertically jointed at intervals, how is it supported, when from the outer face it appears to have no other support than the jambs forming the sides of the aperture?"

The support is usually obtained from a hidden rolled steel joist. R. W. C.

Pupils' Articles.

LONGTON, STAFFS.—PUZZLED PUPIL writes: "There is a clause in my articles to the effect that I shall not practice within a certain radius of the office for a period of five years. I shall be glad to learn whether it is customary in such cases, when the articles are completed, for the architect to retain them for that period, or can I receive them by making another agreement containing the five years' clause? I shall also be glad to learn what the above clause strictly means. Does it refer to the client, the building, or the office?"

The answer to these queries depends so largely upon the exact wording of the articles and the ages of the parties thereto at the time when they were signed, that a local solicitor should be consulted, who could obtain a copy, and consider it at his leisure. The principles of common law may be involved.

G. A. T. M.

Diagrams of Constructive Masonry.

BIRMINGHAM.—STUDENT, R.I.B.A., writes: "I should be glad to know which book supplies the best information for the sheet of drawings required for the R.I.B.A. final examination: One sheet of diagrams of constructive masonry, such as arches, groined vaults, with the projection of arch and vault stones."

Much the best thing to do is to submit a measured drawing of a groined vault, giving both transverse and diagonal sections as well as plans, showing the joints both of ribs and fillings. The best book to consult is Willis's "Vaulting," which however is old and rare.

G. A. T. M.

Arch or Rolled Joists.

PECKHAM, S.E.—F. B. writes: "Would a semi-elliptic arch, 8ft. span and 1ft. rise, of two 4½in. rings of stocks, built in cement mortar, relieve the thrust on the piers better than an ordinary two 4½in. ringed arch with 1in. camber to the foot? Would it be better to make it 9in. on face instead of having two 4½in. rings? Would it be stronger and cheaper to use light r. s. joist instead of having arches? These questions relate to a small warehouse with 18in. walls."

The rolled joists would probably be more suitable for this case, owing to the thrust produced by the arches, say four $4 \times 1\frac{3}{4} \times 5$lbs. rolled steel joists to each opening, with distance pieces bolted between them, and 6in. bearing each end.

HENRY ADAMS.

Colouring Plans on Tracing Cloth.

CROMER.—G. H. writes: "Which is the best way to colour plans on tracing cloth so as to put on the colour evenly over a large space, and to prevent the cloth from being wrinkled?"

Tracings are almost always coloured on the back or opposite side to that upon which the ink drawings are made. In order that the colour may lie evenly, the cloth should first be sprinkled with powdered chalk, which should be well rubbed in with a cloth or piece of blotting paper, any surplus being whisked off. Wrinkles can only be prevented by pinning the edges well down at several places before colouring, not removing the pins till the cloth is thoroughly dry again. Ordinary water colours are used; opaque and earthy colours, such as vermilion, should be avoided. G. A. T. M.

Surveying.

QUESTIONER writes: "How could I learn to read the staff through the level? Are there any books on this subject?"

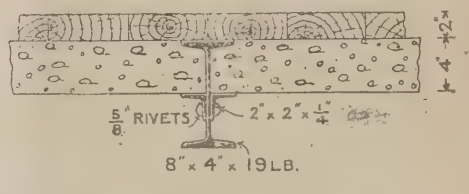
Obtain Middleton's "Surveying and Surveying Instruments."

Prevention of Writing on Walls

LONDON, W.C.—W. E. H. writes: "Is there any effectual method of preventing writing or scribbling on wooden partitions forming divisions between factory W.C.'s? The usual method is, I believe, to sand the woodwork before painting; but the great objection to this seems to be that it leaves a rough surface which does not clean well. As far as I can ascertain there is no material which is proof against writing and cutting except possibly glazed brick partitions, which are costly and occupy considerable space."

This is a question often put, but there is only one answer at all satisfactory, *i.e.*, glazed bricks. Everything else is subject to pencil or knife. Possibly ½-in. rough plate glass in iron frames might answer if space is an object, and there are no cross lights. HENRY ADAMS.

Registration of Architects' Bill.



PLEASINGTON, NEAR BLACKBURN.—NORTH LANCASHIRE writes: "If the above Bill is passed, how will it fare with anyone who has served his articles and has been a paid assistant for two years, but has never practised on his own account and has never passed any examinations except elementary ones in building construction, &c.? Will this person be prevented from practising or from calling himself an architect until he has passed some examination, or will he be a registered architect through having served his articles before the Bill was passed?"

Section 1, Clause 19, of the Bill for the Registration of Architects says: "Any person who was actually practising architecture prior to January 1st, 1899, *or who has served as apprentice, assistant, or practitioner in architecture*, all or either, for seven years in the aggregate, after having attained the age of fifteen years prior to the passing of this Act, shall, on payment of certain fees and signing a declaration, be entitled to be registered."

Sizes of Rolled Joists.

GRIMSBY.—C. E. T. writes: "I shall be glad to know how to calculate the sizes of the rolled joists in a fireproof floor formed of coke-breeze, concrete and rolled steel joists. For example, take a room 30ft. by 15ft., with joists at 2ft. centres and the floor to finish say 8in. thick with wood blocks on top. I should like to know how to calculate the sizes of joists for various spans."

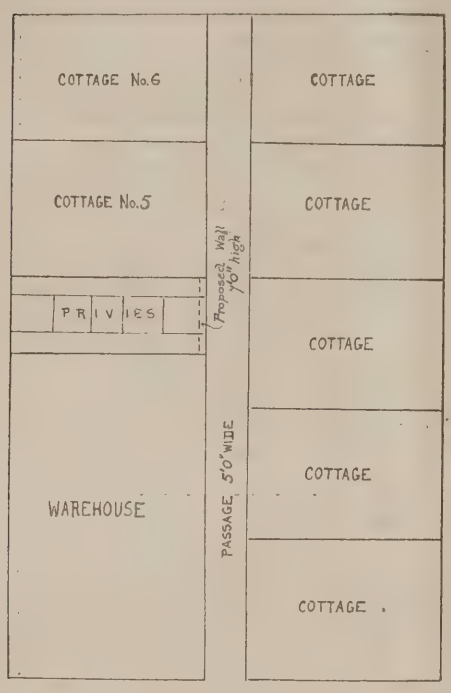
Dwelling-house floors should be strong enough to carry 1¼ cwt. per foot super. and floors of public buildings 1½ cwt. in addition to their own weight. Assuming the floor itself to weigh ½ cwt. per foot super., this will make a total of 2 cwt. per foot super. The joists need not be closer than 3ft. centre to centre, making $15 \times 3 \times 2 = 90$ cwts. on each. For 15ft. span a rolled joist should not be less than 8in. deep, and a steel joist $8 \times 4 \times 19$ lbs. per foot run would carry the load with a factor of safety of 4. The

SIZES OF ROLLED JOISTS.

concrete should be not less than 4in. thick, of 1 Portland cement to 4 coke breeze, arranged as shown in accompanying illustration. Some authorities would make the floor of 6in. concrete with $3\frac{1}{2} \times 1\frac{1}{2} \times 6$ lbs., r.s.j.'s every 18in. level with underside, and estimate the floor as capable of carrying the load with a factor of safety of 6, but the writer prefers not less than 1-24 span for the depth of joist.

By formula $W = \frac{10\,ad}{L}$.

W = breaking weight in tons in centre,
a = area of flange + 1-6 web in sq. ins.,
d = total depth in inches,
L = length of span in feet.



$W = \frac{10 \times 2 \times 8}{15} = 10.67$ tons in centre, or $10.67 \times 2 = 21.33$ tons breaking weight distributed. Factor of safety 4½, safe load distributed $\frac{21.33}{4.5} = 4.74$ tons.

HENRY ADAMS.

Right to Convert Cottages into Warehouse.

SCARBOROUGH.—ENQUIRER writes: "If A buys the block of old property as shown by sketch, would he be able to pull down cottages Nos. 5 and 6 and build a small warehouse not exceeding the present height of cottages, connected with the present warehouse by covering in the space between (where some privies are now built) and putting a wall 7ft. high at the end? If this would not be allowed, could the old cottages be used by clearing out some of the inside fixtures and connecting to the front warehouse as before?"

So far as can be gathered from the information given, the warehouse could be built as proposed by enclosing the space now occupied

CONVERTING COTTAGES INTO WAREHOUSE.

by privies with proper walls, as required under the by-laws for warehouse buildings, and roofing it in, and by uniting each warehouse to the said space by means of proper doors. The querist cannot lawfully convert cottages into a warehouse unless he brings the buildings so converted into conformity with the rules for the construction of warehouses. G. H. B.

Quarry Notes.

The Granite Quarries of Foxdale, Isle of Man, are being opened up, and will be considerably extended. At the present time there are about thirty skilled workmen employed. The Barrule slate quarries have also been recently re-opened, and a party of Welshmen are busily engaged preparing the slate for the market. Trade in the village of Foxdale is now in a fairly good state.

A French Monument from Aberdeen.—Aberdeen granite seems to have taken a firm hold in France, judging from the fact that a large number of orders have been despatched from that country within the last few years. A monument for France, which will be executed in polished Peterhead granite, has been put in hand at the establishment of Messrs. A. Macdonald & Co. The base will measure 12ft. 6in. by 7ft. 4in., while the total height, including the bronze portrait bust with which it will be surmounted, will be 25ft. The carved enrichment will be of an elaborate character, consisting of fruits, flowers and foliage. The base, plinth, cornice and "attique" storey will be richly moulded, and immediately under the bronze bust will be a large bronze shield suspended by floral festoons of the same metal.

Stones for Macadamising.—It is curious that our surveyors and engineers ignore the principle Mr. Macadam laid down with regard to size of stones for paving streets. Macadam directed the public attention to the important fact that angular fragments of hard materials, sufficiently reduced in size, will coalesce or bind, without other mixture, into a compacted mass of stone, nearly impervious to water, which, being laid almost flat, so as to allow of carriages passing freely upon all parts of the road, will wear evenly throughout. "Every piece of stone put into a road which exceeds an inch in any of its dimensions is mischievous," is Macadam's first principle, which, however, is regularly ignored. The disgraceful state of the Victoria Embankment emphasises the point; the engineers of the London County Council have adopted a $2\frac{1}{2}$-in. gauge and even that is not insisted upon. Consequently, binding material in the form of gravel has to be used, forming the road of two substances—one yielding, the other rigid—which gives the irregular surface we are familiar with.

A Church for £12.—It is seldom that one hears of a church being sold, and for so small a sum as £12; but such an incident has taken place at Norton (Malton). The church is that of St. Nicholas, and the purchasers are the Norton Urban Council, who are about to pull down the edifice and use the stones in the construction of an open-air swimming-bath for the town. It is said that there is a lot of old oak pews and other woodwork in the building which will doubtless be valuable for purposes other than those connected with the new swimming-bath, so that the Council may be congratulated on having got "a bargain." The church is not an old one, and its fate, after an existence of something like eighty-five years only, is anything but a compliment to its architect and builders. Judging from its plain, weather-beaten exterior, its dilapidated roof, and its generally neglected appearance, one would think the church had stood for centuries. It was built at one of the worst epochs of church architecture in this district, and when church affairs were at a dead level in Norton. The parish church of Norton which has taken the place of the one just sold is not yet finished, although it has been used for worship since 1894. The complete scheme represents a cost of £12,000. Seating accommodation has already been provided for 420 persons, and when the tower and other additions are made there will be room for 650 worshippers.

New Patents.

These patents are open to opposition until January 7th

1899.—Theodolites.—21,889. W. P. THOMPSON, 332 High Holborn, London, W.C. (communicated by R. Rech, Wetzlar, Germany). This invention transfers images of the azimuth and altitude scales into the plane of vision of the telescope in such a way that the images and the object can be observed at the same time. The apparatus consists of microscopes with micrometric scales, the images of the scales being brought into the plane of vision through the horizontal axis of the trunnions of the telescope by means of glass prisms and convex lenses to the eye tube, where they are clearly visible at any position of the eye-piece.

Valve Water-closets.—22,605. H. L. DOULTON, Lambeth Sanitary Engineering Works, London, S.E. The opening of the supply and discharge valves is effected in one operation by means of a press-down or other valve. The discharge valve is closed simultaneously with the supply valve by a force wholly or partly communicated from the supply valve.

Plumbers' Shave-hooks.—22,631. W. J. WAYLAN, 284 High Street, Sutton, Surrey. The hook consists of a handle, a shank with a fixed blade at the end, and an adjustable gauge. The tool can be used in awkward situations, and affords absolute accuracy in working.

Hollow Bricks.—25,214. J. C. SELLARS, 68 Bridge Street, Birkenhead. Refuse-destructor material is ground and mixed with a small quantity of lime, cement and water, and in a semi-dry condition is pressed into a mould having a stationary perforated core and a perforated base to allow air to escape and dirt to be removed. The blocks are afterwards treated with silicate of soda and dried.

1900.—Fireproof Floors.—1,803. W. J. CHANT, 98 Drayton Gardens, South Kensington, S.W. The ceiling is composed of cast sheets of plaster (having a stiffening of wire) attached to iron bearers that stretch between the joists. The wooden centering used has wooden or iron ribs bearing on the lower flanges of the joists. It is claimed that this construction is simple, reliable and expeditious.

Paint Removers.—14,114. A. KLEE, Viernheim, Hessen, Germany. This paint remover consists of water, 50 parts; linseed oil, 10 parts; Venice turpentine, 20 parts; soda, 5 parts; spirits of wine, 15 parts.

The following specifications were published on Saturday last, and are open to opposition until January 14th. A summary of the more important of them will be given next week. The names in italics within parentheses are those of communicators of inventions.

1899.—22,173, PEAKE, hot-water boiler. 22,205, TWEEDIE, trap and overflow fittings for lavatory basins, sinks and baths. 23,003, BLAIR, BLAIR AND BAILLIE, evaporators for producing fresh water from salt or impure water. 23,088, WILSON, regulators for gas burners. 23,660, WILSON-SMITH, methods of decorating the surface of paper, &c., in imitation of mosaic or veining. 23,794, CO-OPERATIVE PADLOCK SOCIETY, LTD., AND LAWTON, lever locks. 24,096, SNELL, burners used for incandescent gas lighting. 24,124, WISE (*Kitson*), lighting and heating apparatus. 24,375, HUSON, chemical chimney cleansers. 24,489, SHAW, drawing and other pins. 24,612, SELLARS, manufacture of building tiles and blocks. 24,840, FORD, hatchets, picks, hammers, &c. 25,250, BREWER, BREWER AND SPONDER, sashes and frames. 25,392, LACEY, apparatus for lifting sewage and other liquids. 25,526, RITTMAN (*Soc. Josz et Fils et Cie.*), coverings for walls and ceilings. 25,723, DEAN, extension ladders.

1900.—164, STEAD & CARR, electric incandescent lamps. 426, FISHBURN, apparatus for elevating or lowering building materials. 1,958, WINTERFLOOD, water heaters and automatic valve attachments for them. 2,647, KILLON, apparatus for the automatic intermittent discharge of sewage from filter beds. 2,756, MORGAN, method of fixing handles to files and other tools. 5,706, HALKES, guards for circular saws. 6,533, MARCHANT, chimney pots. 6,816, STANLEY, drying conveyors. 7,018, FLETCHER, lift apparatus. 7,019, FLETCHER, lift apparatus. 8,074, MÖBUS, mould-making machines. 12,862, LAKE (*Jewell Export Filter Co.*), production of reagents specially designed for purifying water. 13,128, BRUNS, moulding and stamping table for concrete roofing tiles. 13,491, GÜSSOW, manufacture of artificial stone. 13,694, SYKES, drawing scales. 13,761, BOULT (*Marsden*), perforated plates for building and other purposes. 13,802, KUHNERT, apparatus for separating stones from loam and clay. 14,034, MEISSNER, apparatus for the production of acetylene gas. 14,571, HANNA, sand-screening machines. 14,938, WERNICKE, apparatus for filling moulds with cement, artificial stone, &c. 14,954, LAKE (*H. B. Smith Machine Co.*), sandpapering machines. 15,594, JOHANSSON, door latch. 15,780, SIMON, roofs of buildings. 16,220, WILD & RIGBY, apparatus for the purification of smoke. 17,033, LUKOWSKY, device for use in enlarging or reducing maps, plans, &c. 17,432, BAUKE, lifts. 17,470, GALLOWAYS, LTD., & BAYLISS, compound safety and low-water valves. 17,684, WANGELIN, float valves for water cisterns.

Zion Church, Rhigar, has had three new stained-glass windows introduced, the work of Messrs. Heaton, Butler and Bayne, of London

THE USE OF ROLLED JOISTS IN CONSTRUCTION.

By A. T. WALMISLEY.

THIS was the title of a paper read at a joint meeting of the Architectural Association and the Institution of Junior Engineers on Friday, November 23rd.

Mr. A. T. Walmisley, in introducing his paper, referred briefly to the theory of iron joist construction. When a girder had to be dealt with, he said, the first thing to understand was the moment of resistance, and the consideration of the moment of inertia had to be entered into. When a cantilever was loaded the upper portion became in tension and the lower in compression. For a beam the argument was the same. If the upper fibre was in tension and the lower in compression there was an intermediate point upon which there was no stress: this was called the neutral axis. Supposing we did not employ the ordinary formula but divided the beam, say of 12in. by 6in. section, into two horizontal layers the bearing area would be deduced from the distance of its centre from the neutral axis, which would give in the beam of typical section 648; dividing it into four layers the result would be 810; the more layers the section was divided into the nearer the true result, 864, was approached. He then continued as follows:—

If S = safe stress per sq. inch in the outside fibre of a beam and x = its distance from the neutral axis and b = breadth and t = thickness of layers in section, then bt = area = a, and if y or y' = distance of centres of area from the neutral axis, moment of resistance of outside plate or layer = $(a \times y)\frac{y}{x}S = f(a \times y)$, because the strain being zero at the neutral axis and a maximum at a distance x from it, it will at a distance y from the neutral axis have a unit value of $\frac{y}{x}S$, which multiplied by the area, gives the total strain in the layer acting at a distance y from the neutral axis.

$(a \times y)\frac{y}{x}S$. Now x and S in this equation being constant for every area in the section, they can be eliminated and applied after summation. The formula then gives what is called the moment of inertia = $I = Ay^2$ and $\frac{I \times S}{x}$ = moment of resistance.

Typical Section, 12*in.* × 6*in.*—Calculated by the formula $\frac{bd^3}{12}$ (Molesworth) we find

$$I = \frac{6 \times 1728}{12_2} = 864$$

and dividing the section into 2, 4, 6, 8, 10, or 12 equal layers, and calculating from the distance of the centres of the areas of the upper ones from the neutral axis

$$I = 36 \times 3^2 = 324 \times 2 = 648$$
$$I = 18(4\cdot5^2 + 1\cdot5^2) = 405 \times 2 = 810$$
$$I = 12(5^2 + 3^2 + 1^2) = 420 \times 2 = 840$$
$$I = 9(5\cdot25^2 + 3\cdot75^2 + 2\cdot25^2 + \cdot75^2) = 425\cdot25 \times 2 = 850\cdot5.$$
$$I = 7\cdot2(5\cdot4^2 + 4\cdot2^2 + 3\cdot0^2 + 1\cdot8^2 + \cdot6^2) = 427\cdot68 \times 2 = 855\cdot36.$$
$$I = 6(5\cdot5^2 + 4\cdot5^2 + 3\cdot5^2 + 2\cdot5^2 + 1\cdot5^2 + \cdot5^2) = 429 \times 2 = 858.$$

The above trials show that in proportion to the number of horizontal sections taken, the nearer to the truth will be the result.

The Chemistry of Steel.

The late Sir William Siemens, addressing the Iron and Steel Institute in 1877, stated that the use of steel for structural purposes could only be said to date from the year of the Great Exhibition of 1851. Its manufacture is now well understood. It is found to be a complex structure, and not the homogenous mass it is often supposed to be. Addressing the Iron and Steel Institute this year (1900) Sir William Roberts-Austen stated that "in 1,000 parts of steel, 997 parts, more or less, may be iron and the rest carbon," but that the result of the union is a metal that is more widely used and has more varied attributes than any other ial.

The interdependence of small percentages of matter on the larger masses in which such minute contributions are hidden is one of the chief studies of metallurgists of the present day, and the chemistry of steel shows the effects produced by the existence of phosphorus, silicon, manganese, and sulphur in the material, rendering some kinds of steel comparatively soft, while others were extremely hard. The mode adopted for either rapid or slow cooling was seen to have an influence. The committee appointed by the Board of Trade to inquire into the loss of strength in steel rails through use on railways, consequent on the St. Neots accident of December 10th, 1895, after four years' labour, in their report issued this year state that, as regards chemical composition, they do not think it desirable to insist upon too high a proportion of carbon, manganese, or silicon in the steel, having regard to the ordinary contingencies of manufacture and the greater susceptibility of high carbon steel to thermal influences, but beyond giving tabular results of investigation of individual specimens, the committee, while establishing the conclusion that the evidence is not sufficient to justify a decisive verdict respecting percentages, nevertheless insist on the importance of securing as low a proportion as possible of phosphorus, sulphur, and silicon in steel which is to be manufactured into rails, and these precautions would apply in a similar way to rolled joists.

The St. Neots rail was a Bessemer steel (80lbs. per yard) bull-headed rail, laid in 1873 on the Great Northern Railway up line, and transferred to the down line after thirteen years' service on the up line during repairs at some date not recorded. Its failure may have been due to local stresses unavoidable at the joints and independent of the chemical composition of the steel, but which joints need constant inspection.

Although iron does not combine with carbon at ordinary temperatures, yet the union may be effected when brought into contact at a red heat. Mild steel containing a proper percentage of carbon is produced by the Bessemer as well as by the open hearth processes both with either acid or with basic lining to the convertor or hearth. The open hearth process is more under control, and gives more time to adjust the composition than the Bessemer converter, and hence is generally preferred. In the Bessemer or pneumatic process molten pig-iron is blown through, the carbon and other elements burned out, and then the desired proportions of carbon and manganese are added, and the whole process is over in, say, twenty minutes. Hematite pig-iron is used in connection with acid linings. With silicious linings such as ordinary firebrick, basic slag would combine with it and eat it away. Calcined magnesian limestone is generally used for a basic lining, and hence the process is called basic. We have the treatment of pig-iron with certain classes of iron ores without the addition of scrap, according to the direct open-hearth process of the late Sir William Siemens, and the fusion of a mixture of pig and scrap iron or scrap steel in the open-hearth process of Messrs. Siemens-Martin, in which the steel is dead melted and the process allows time to draw samples for testing and time to doctor up the mixture as required. Pig irons containing but little carbon or silicon are preferable for the open-hearth process. Phosphorus aids cold shortness, *i.e.*, breakage cold and unexpectedly, while sulphur aids red shortness. A deficiency of silicon results in inferior metal. Only the purer kinds of pig-iron can be operated upon in silicious or acid-lined furnaces, while with basic linings more impure phosphoric pig-irons can be used, and the slag of the basic process contains from 10 to 18 per cent. of phosphoric acid, which is ground up for use as a fertiliser. The higher the carbon the higher the tensile strain. This can be regulated in the open-hearth process without expense. For thin material the carbon is kept low, and for thick material it is kept high. The operation of rolling hardens it. The sulphur and phosphorus should be below ·06 per cent. The lower the steel in phosphorus the less susceptible it is to crystallisation when punched. Experience shows that the lower the phosphorus, the other elements being the same, the less is the steel affected by cold working. The connexions in all steel work is preferably made in holes carefully drilled.

Messrs. Dorman, Long and Company (Middlesbrough) adopt a proportion of between 0·16 and 0·25 per cent. carbon in their steel by the Siemens-Martin process. Owing to the supplies of the best hematite ores becoming scarce, the quality of this kind of ore is inferior to what it was a few years ago, and it is very difficult to keep the sulphur and phosphorus below expedient limits. This is one of the reasons which has led Messrs. Dorman, Long and Co. to adopt the manufacture of steel from Cleveland iron, the phosphorus being eliminated by lime and the sulphur by calcium chloride. They find that they are able to obtain better results than they could with the old hematite iron, and by keeping records of frequent analyses, and having meanwhile the furnace under control, they supply the sections which give satisfaction.

At the Earl of Dudley's Round Oak Iron and Steel Works, Brierley Hill, they adopt the basic open hearth process, and can produce anything from ·1 to ·3 carbon that punches cleanly and works satisfactorily. The Shelton Iron and Steel Company also adopt the basic open hearth process.

Shape of Joists.

A large number of joists used in construction are too shallow. The proportionate depth to the span should be $\frac{1}{15}$, but should never be less than $\frac{1}{20}$ of the span. There is considerable advantage of depth over width. In the common form of placing one stock section over another, the flanges which are united in the centre do not materially assist the moment of inertia of the section. Hence the tendency to deflection obviated by the use of two joists, one on the other, could be better provided for by the adoption of a made-up girder with angle-irons and plates in which the metal of the double centre could be transferred to the top and bottom flanges. When girders have to carry a floor to which a plastered ceiling is to be suspended, comparative stiffness is indispensable to prevent sagging and the consequent cracking of the plaster, and should be designed under such circumstances so that the deflection does not exceed $\frac{1}{30}$in. per foot of span, but this ratio might even be reduced with advantage. Makers' catalogues show the sizes and weight of joists kept in stock, and in some cases add the safe distributed loads over various spans for each joist, but do not state the breaking strain assumed, or if they do give this they do not add the factor of safety taken to arrive at the amount of stress per square inch. Hence it is not generally fair to say that because one list gives higher loads than another list that the joists are superior. In each case the designer must determine the safe working load for himself, and see that both the flanges and the web are each capable of sustaining their due proportion of strain.

The joists sometimes come in from the mills not as true as one could wish, the flanges not being parallel. This is more noticeable in the wider sections, the 8in. by 6in. especially. Such wide sections, also 9in. by 7in., are more suitable for stanchions than girders. When a wide dimension is needed for girder work, for the support of a wall or other purposes, two rolled joists are introduced side by side, top and bottom flange plates being added to form the connection. As a rule, in single joists the width of the flange should be sufficient to resist flexure in a horizontal, plane, or lateral bending. When the boom is of insufficient width the girder will fail by the lateral deflection of the top bay or boom rather than vertical buckling.

Resistance to Lateral Flexure.

Professor Rankine has deduced the following formulæ for the ultimate strength of the top booms of small girders as regards resistance to lateral flexure:—

$$t = \frac{f}{1 + ar^2}$$

where t = the ultimate average thrust per square inch upon the flange area; r = the ratio of length of flange to width; f = 16 tons per square inch or such other value to suit the

material in use; a = a constant which equals $\frac{1}{5000}$ for a flat boom.

When more than a single girder is employed, if the circumstances are such as to admit of the flanges being braced horizontally together like a horizontal lattice girder, not only material may be saved, but the advantage of the inside surfaces of the girders that are so connected is secured for inspection and for facility of forming the connections.

Generally speaking, the width of the upper flange of a girder, when not stiffened laterally by additional connections, should be $\frac{1}{30}$ to $\frac{1}{40}$ of the span, so that if the depth is assumed as $\frac{1}{12}$ of the span, the width would be $\frac{2}{5}$ of the span, showing that if the usual stock sizes be taken of 10in. by 5in., or 12in. by 6in., the proportion of half the depth for the width of flange is ample. The width of the lower flange needs to be such as will give a proper bearing on the piers, or if the beam is suspended from the top flange, a sectional area to resist the tension produced by the loads. It is useful to remember that in long girders the web of a joist is more likely to fail near the points of support than in the centre, not only on account of the action of shearing strain, but on account of the conditions of rolling. Hence at the works it is found well to crop off the ends after rolling long lengths so as to obtain a more uniform strength of section throughout.

In connecting rolled joists at right angles to one another, when one is "machine special notched," a good distributing bearing for the transverse joist upon the lower flange of the longitudinal joist is secured at the connection.

In considering bearings, girders should rest on a wall, and not merely upon a pier attached to a wall. The writer has seen girders resting upon what appeared like a pier in plan, but which had simply been brickwork corbelled out.

The higher the wall the less the pressure from the girder upon the ground.

Where joists rest on timber, masonry, or brickwork, bearing plates are invariably introduced to distribute the weight, and such plates should be thick enough to countersink the rivets of attachment to the joists on the under side of the bearing plates. When such plates are set back from the front edge of the wall or stone on which they are placed they exercise the same effect as chamfering the edge of the template.

Size of Joists.

In the Paris Exhibition of 1867 a rolled beam was exhibited measuring 1 metre (39⅜in.) in depth, 10 metres (33ft.) in length, and weighed 2½ tons. This beam, instead of being rolled in the usual way, was subjected to the pressure of four rollers, by which process the quality of the iron in the flanges was preserved as well as that of the web.

The Carnegie Steel Company roll a beam 24in. by 7in. to 80lbs. per foot and moment of inertia = 2,087. Their joists generally present a good finish, free from surface imperfections and straight. The American joists seem to contain a slightly larger amount of phosphorus in their composition than the British manufacture. They give, for example, a test of 0·08. Ours is about 0·06. The Americans have, however, practically discontinued manufacturing acid open hearth steel, and now make only basic steel, which they assert to be purer chemically. The American joists are at present cheaper than the English, but this, of course, is only peculiar to the moment.

French joists to a reasonable specification are fairly satisfactory, but are not much cheaper than our own when the cost of carriage is added. They adopt the Siemens-Martin basic system. There is nothing fixed for the percentage of carbon, phosphorus, silicon, manganese, or sulphur. Tests are applied by the engineer during use to test hardness and other requirements. They specify 32 kilogrammes per square millimetre, with an elongation 8 per cent. for iron and 42 kilogrammes per square millimetre (26·6 tons per square inch) for steel.

The first national work in this country in which foreign iron was employed was the Natural History Museum, South Kensington, about the year 1869. The term "Belgian joist" is a generic term, as joists are made in France and Germany as well as in Belgium, and sold as foreign joists.

Results of 1,200 *Tests of Foreign Steel Joists.*

Limit of elasticity	Maximum	69·0%.
	Average	64·1%.
	Minimum	60·0%.
Ultimate stress in tons per square inch	Maximum	29·1 tons
	Average	28·08 ,,
	Minimum	27·2 ,,
Elongation per cent. in 8in.	Maximum	28·0%.
	Average	24·39%.
	Minimum	20·5%.
Reduction of area per cent.	Maximum	60 2%.
	Average	50·53%.
	Minimum	42·4%.

The above were German manufacture. Observe how even are the results recorded, due probably to the fact that the Germans are good chemists.

As to British, German, Belgian, and American make, all these countries have manufacturers whose output is thoroughly good and reliable. There is no difficulty in obtaining foreign material that will stand the required tests, and the result of foreign competition has been that many of the British rolling mills who roll joists are now better equipped than formerly. At the same time, the foreign ordinary commercial joist delivered into this country, from Belgium in particular, is not a good joist, and frequently in some foreign joists the web is thickened to obtain the weight at the expense of a minimum flange. It must be remembered that wrought-iron does not flow like cast-iron, and it is difficult to get the material pushed up in rolls where the flanges are wide compared with the depth of joists. Iron joists are generally of greater sectional area than steel. They are the same depth and width, but weigh more per foot run on account of sectional area. Thus iron joists weighing respectively, 56, 35, and 13lbs. for 12in. by 6in., 10in. by 5in., 5in. by 3in. weigh in steel 44, 30, and 11lbs. per foot run.

Railway companies, for patriotic reasons, and more particularly for the benefit of their traders, usually insert a clause in their contracts that all materials provided by a contractor are to be obtained from traders who give their traffic to the company, and conveyed over the railways and canals (if any) belonging to the company. The manufacture depends mainly on the specification, and therefore both British and foreign steel may or may not be good, as the material known as mild steel may have almost any strength between that of hard steel and that of wrought iron.

A Safe Co-efficient.

The committee on the use of steel in railway structures appointed by the Board of Trade to consider the practicability of assigning a safe co-efficient, reported in 1877 that the steel employed should be cast steel, or steel made by some process of fusion, subsequently rolled or hammered, and that it should be of a quality possessing considerable toughness and ductility, and that a certificate to the effect that the steel is of this description and quality should be forwarded to the Board of Trade by the engineer responsible for the structure. Also that the greatest load that can be brought upon the bridge or structure, added to the weight of the superstructure, should not produce a greater strain in any part than 6½ tons per square inch.

As in the use of mild steel, the extension per ton per square inch is practically equal to the compression, it follows that the neutral axis of a section of steel strained transversely will be in the centre of gravity of its section; but as in wrought and in cast-iron sections the unit stresses, particularly in the latter, vary in the case of tension and compression, the moment of inertia must be calculated from a neutral axis not coincident with the centre of gravity.

The qualities required in a steel or iron structure being chiefly of a mechanical nature, it is reasonable that the test should be mechanical, and, provided these tests are satisfied, the beginner does not trouble himself about the chemical constituents. Tests are provided to detect brittleness and to secure toughness, combined with ductility and malleability, and the result of experiments show that the tensile resistance and limit of elasticity are the main objects of inquiry.

Tensile strength 27 tons to 31 tons per square inch ultimate with elongation of 20 per cent. in 8in. lengthways and crossways of the same.

Specification for mild steel plates and sheets as adopted by the Great Western Railway Company:—

1. All plates to be of British manufacture.
2. All plates and sheets to be of the exact dimensions ordered, and to be uniformly throughout of the thickness specified.
3. All plates and sheets to be flat and free from blisters, scale, laminations, buckles, and all other defects.
4. All plates and sheets to be of such quality as to weld perfectly.

Strips cut lengthwise and crosswise to be capable of standing the following tests:—

Tensile Test.—Ultimate tensile strength to be not less than 24 tons nor more than 28 tons per square inch, with an elongation of at least 22 per cent. when the thickness of the sample is more than $\frac{5}{16}$ of an inch, and with an elongation of at least 20 per cent. when the thickness is $\frac{5}{16}$ or less; elongation in each case to be measured over a length of 10in.

Temper Bending Test.—Strips 1½in. wide, heated uniformly to a low cherry red and cooled in water of a temperature of about 80 deg. Fahrenheit, to stand bending in a press to a curve the inner radius of which is equal to the thickness of the plate.

Cold Bending Test.—Strips 1½in. wide to stand bending cold in a press to a curve the inner radius of which is equal to the thickness of the plate.

Punching Test.—The material to be tested for ductility by punching cold a group of holes ⅝in. to ¾in. diameter, the edges of which shall not be more than $\frac{3}{16}$in. apart.

All mild steel rivet, channel, angle, T, and other bars to be of such quality as to weld perfectly, and to have an ultimate tensile strength of not less than 24 tons, nor more than 28 tons per square inch, with an elongation of at least 25 per cent., measured over a length of 10in.

All rivet bars to be rolled exactly round to gauges to be supplied by the railway company.

The material to be tested for ductility by being bent cold under a steam hammer; also by punching cold a group of holes ⅝in. to ¾in. diameter, the edges of which shall not be more than $\frac{3}{16}$in. apart.

Rivet bars, in addition to the tensile tests, must stand bending double, both hot and cold. The head heated to redness must stand flattening until its diameter is three times the diameter of the bar without cracking at the edge.

All wrought-iron plates, sheets, and bars to be of British manufacture, tough, fibrous, and of the highest smithing quality.

All plates, sheets, and bars to be of the exact dimensions ordered, and to be uniformly throughout of the thickness or section specified.

All plates, sheets, and bars to be free from blisters, scales, laminations, buckles, twists, and all other defects. All plates and sheets to be flat.

All plates, sheets, and bars to be of such quality as to have an ultimate tensile strength of:—

	Tons per sq in.	Elongation.
Round and square bars and flat bars less than 6in. wide	23	with 20 p.c. in 10in.
Angle, tee, channel, and H bars and flat bars over 6in. wide	22	with 12 p.c. in 10in.
Plates with the fibre	22	with 10 p.c. in 10in.
Do. across the fibre	18	with 3 p.c. in 10in.

and to admit of bending round a radius equal to the thickness when hot through an angle of 125 deg. with the grain, and 100 deg. across the grain, and when cold as follows:—

Thickness of plates .. .. .. in.	1 and ⅛	⅝ and ⅛	⅝	⅞	1	1⅛	1¼	1⅜	1½	1⅝	1¾	1⅞	2	2⅛	2¼
With the grain, through an angle of .. deg.	15	20	22½	25	27½	30	35	42½	50	60	70	75	85	95	100
Across the grain, through an angle of .. deg.	5	7½	10	10	12½	12½	15	17½	20	25	30	30	40	50	50

The whole of the iron to be inspected and tested before leaving the manufacturers' works.

The Carnegie Steel Company, of America, specify for structural steel an ultimate strength of 60,000 lbs. to 70,000 lbs. (26 78 to 31 24 tons) per square inch.

Elastic limit, not less than one-half the ultimate strength. Elongation, 22 per cent.

Bending test, 180 deg. to a diameter equal to thickness of piece tested without fracture on outside of bent portion. The elongation shall be measured on an original length of 8in., except when the thickness of the finished material is $\frac{5}{16}$in. or less, in which case the elongation shall be measured in a length equal to sixteen times the thickness; and except in rounds of $\frac{5}{8}$in. or less diameter, in which case the elongation shall be measured in a length equal to eight times the diameter of section tested.

The London and North-Western Railway Company specify that all steel shall be of British manufacture, produced by the Siemens-Martin open hearth process, and of such quality as to withstand the following tests:—

Ultimate tensile strain not less than 28 tons per square inch, contraction of area at fracture for same not less than 40 per cent., extension in a length of 10in. not less than 20 per cent.

Some authorities prefer to take the elastic limit rather than the ultimate strength of the material, but as they then employ a proportionately smaller factor of safety, the result is practically the same.

Stanchions.

It requires no long description to prove that a long and slender column always gives way by bending, but the reasons are not clear until we consider the question in a negative form and inquire why it should not bend. A slender rod with rounded or hinged ends will bend like a bow, and the lateral resistances opposed to such bending will be similar to the vertical resistances offered by a rod supported at both ends over a free span when laid as a beam and loaded. In the latter case we know that the deflection is proportional to the amount and disposition of the load, so that to produce a great deflection we have to introduce a proportionally great load, the elastic resistance of the beam bearing a definite ratio to its deflection. In a solid block, viewed as a short column free from flexure, the element of compressive stress only prevails, and in a long column fixed at the ends, the reasoning is again modified by the points of contra-flexure that have to be considered. In every material the strength diminishes rapidly as we advance from short to long columns, but the reduction is more conspicuous in the cast-iron and the strong steel than it is in the softer metals. In the case of free ends cast-iron is only economical up to 3½ diameters and for ends fixed up to 7 diameters, while for heights exceeding this ratio mild steel is preferable to the use of either cast- or wrought-iron. In further considering the question of flexure in an upright column, there being no apparent transverse force to produce the bending, the result can only be caused by the ends tending to approach one another, and the condition of things resembles the action of a bow in which the ends are united by a member in tension, so that if we can determine the tension produced in the member uniting the ends, we shall have found the resistance that the bent column opposes to the load on its head. This evidently must depend more upon the elastic stiffness of the material and the dimensions of the columns than upon the crushing strength of the material. The form of the section is important, and a rolled joist section is preferable to the channel  or  section sometimes employed with its web or back placed against a wall, because the compressive stress is more equally distributed over its section. An open or  section also has this advantage for use as a stanchion, compared with a round hollow column, that the whole surface can be seen and its thickness checked without the need of drilled holes to prove that the thickness is uniform.

A slender column is naturally a very weak one, and in order to obtain a satisfactory adoption of its introduction in a structure we must provide against the action of flexure, which is the source of its weakness. This may be effected by the same means as in a girder namely, by removing the metal from the centre and placing it as far away from the axis of the stanchion as possible. The value of the development of material as in a girder, also applies to a stanchion, so that by the adoption of four separate legs braced together like a lattice-girder we may so develop the material in a filamentary form as to considerably increase its efficiency. In a stanchion of any section the resilient force R is proportional to the modulus of elasticity, but is independent of the ultimate strength of the material. Thus a long stanchion of the strongest steel would vary little from a similar stanchion of wrought iron, because the modulus of elasticity is nearly the same in both these materials. However great the ultimate resistance of the steel may be, the crushing stress will inevitably be reached at some period of the increasing bending strain if only the load is sufficient to overcome the resilient force of the bow and to set up the ever-increasing deflection. When this deflection begins to act, the stanchion may be considered as having failed for all practical purposes, no matter what may afterwards happen to it during the course of the buckling process. A steel stanchion would theoretically take a greater ultimate deflection than the wrought-iron stanchion before it became actually crushed or crippled on the concave side, but the breaking weight would be nearly the same for both materials. When struts of different sections are ranged together according to the radius of gyration, the results of experiments agree together as closely as could be expected; but if struts of equal diameter and of different patterns of cross-section are ranged together their strengths vary. In short stanchions the superior strength of the steel will come into play, and in a stanchion of unequal elasticity it will come into play to some extent at all ratios of length to diameter.

Professor T. Claxton Fidler, in his treatise on "Bridge Construction," states that there can be no doubt that amongst the different sections of rolled iron bars or *built struts* the radius of gyration should be taken rather than the outside diameter as the true measure of stiffness.

I = moment of inertia = sectional area of beam or stanchion × the square of the radius of gyration $(r)^2$.

Therefore, dividing the force R by the sectional area in square inches, we have the resilient force in pounds per square inch of the section of the strut expressed by—

$$p = \frac{R}{A} = \pi^2 E \frac{r^2}{l^2},$$

and this denotes the theoretic breaking weight of long stanchions in pounds per square inch, or the load which is sufficient to overcome the resilience (or the act of springing back, popularly known as "rebounding") of the bow, and to produce indefinite deflection.

Stanchions.	Ends Fixed.	Ends Free.
Cast-iron (solid) rectangular	$P = \frac{35}{1 + (\cdot0037)\,H^2}$	$P = \frac{35}{1 + (\cdot0148)\,H^2}$
Wrought-iron (solid) rectangular	$P = \frac{16}{1 + (\cdot0005)\,H^2}$	$P = \frac{16}{1 + (\cdot002)\,H^2}$
Wrought-iron (solid) angle	$P = \frac{19}{1 + (\cdot0011)\,H^2}$	$P = \frac{19}{1 + (\cdot0044)\,H^2}$
Mild steel (solid) round	$P = \frac{30}{1 + \left(\frac{1}{1400}\right)H^2}$	$P = \frac{30}{1 + \left(\frac{1}{350}\right)H^2}$
Mild steel (solid) rectangular	$P = \frac{30}{1 + \frac{1}{2480}H^2}$	$P = \frac{30}{1 + \left(\frac{1}{620}\right)H^2}$

Note: P = Crippling stress per square inch in tons. $H = \frac{L}{D}$ = ratio of length to width in direction of plane of flexure. P × area = breaking stress of given section.

THE DISCUSSION.

Prof. Henry Adams, in proposing a vote of thanks, said that Mr. Walmisley had suggested that the depth should be one-twelfth the span; but that would hardly be suitable to architects, and, as a matter of fact, they made a span in feet equal to twice the depth in inches, though in a fireproof floor of iron and concrete there was a still greater ratio of span to depth.

Mr. Percival Marshall, President of the Institution of Junior Engineers, seconded the vote of thanks.

Mr. B. Blount thought that architects and engineers who were troubled at times by failures not readily explicable should remember that a mere specification of the mechanical properties of steel, and even its chemical composition, was not everything; they must also take note of the microscopical character of the metal.

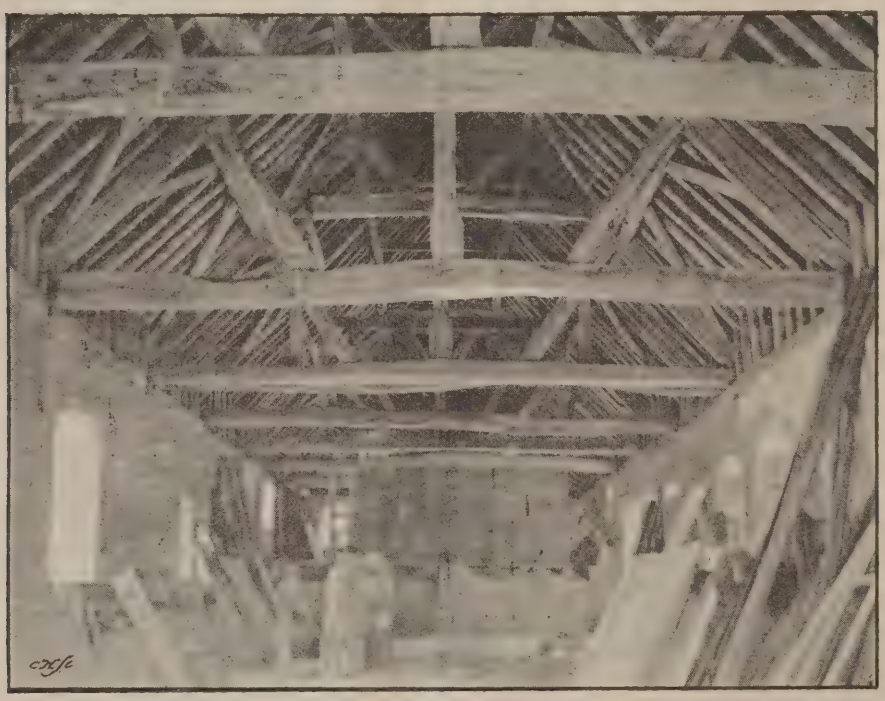
Mr. R. J. Gifford Read having spoken, Mr. P. J. Waldram warned architects to be careful to ascertain the market price when specifying riveted work, it being sometimes more expensive to put less material in the joists than more material of a certain character, and it was well in extensive work to get an estimate before deciding on riveted-up work. In order to develop the full strength of the plates in such work the rivets should be designed, not guessed at.

Messrs. H. Lovegrove, W. H. Shephard, H. Satchell, H. Young, junior, and W. H. Seth-Smith also spoke, and the vote of thanks having been recorded, Mr. A. T. Walmisley, in reply, said it never did to have a cast-iron beam fixed at both ends, because it was not made to take tension and compression in the same flange. Engineers, although they recognised some advantage in a stanchion or girder fixed at both ends, preferred, where possible, to have them free at both ends, because the stresses were then more definite.

Surveying and Sanitary Notes.

The death of Mr. James Lovegrove, A.M.I.C.E, is announced. Deceased was until June of last year the chief surveyor to the late Hackney Vestry.

The Widening of Leadenhall Street, E.C., is proposed to be carried out. No step can be taken for the moment in the direction of acquiring the property, and as yet the London County Council have not endorsed the proposal. At the same time, the letter presented to the Court of Common Council stating that the fullest consideration will be given to every application made for a grant when a favourable opportunity presents itself for acquiring properties shows that the authorities at Spring Gardens realise the importance of the improvement, and are ready to render financial assistance. The street is already too congested, and when the rebuilding of the Crutched Friars area is completed and the northern approach to the Tower Bridge is finally constructed, there will be a yet further augmentation of traffic. The outlay is estimated at £637,000.



The Plumbers' Company held its annual dinner in Fishmongers' Hall last week. About 170 gentlemen were present. The Master (Mr. Charles Hudson) took the chair, supported by the Warden (Alderman R. Hind), the Renter Warden (Sir J. Knill), Sir J. Monckton, Mr. J. Skirrow (president of the Master Plumbers Association), Mr. H. Hamilton (president of the Operative Plumbers' Association), and other gentlemen. The Warden urged that the Plumbers' Registration Bill, hitherto promoted by the Company, should be taken up by the Government, because its principle had been approved in three sessions of Parliament and by two Ministries, and because experience had proved that a private member could not carry it in the face of the twelve o'clock rule. Mr. R. Crawford (Glasgow) complimented the company on having done something to form a confederation of local authorities who would, he trusted, think less of the ancient claims of property and more of the modern claims of life and health.

Bricks and Mortar.

APHORISM FOR THE WEEK.

"*We have seen in modern times the power of Ptah developed in a separate way, which no Greek or Egyptian could have conceived. It is the character of pure and eyeless manual labour to conceivee everything as subjected to it; and, in reality, to disgrace and diminish all that is so subjected; aggrandising itself, and the thought of itself, at the expense of all noble things.*"—RUSKIN.

Our Plates. CONTINUING our series of London street studies, we publish this week a drawing by Mr. Sydney Newcombe of No. 63 Sloane Street. This is an old house which has been remodelled from designs by Mr. Fairfax B. Wade, architect. The old stock-brick facing remains, and the bay window, window dressings and entrance have been carried out in Monk's Park stone. The contrast between the stock brick and stone dressings is very slight, and produces a quiet effect which is particularly pleasing and appropriate in a private residence. The design by Mr. H. Wilson for the new staircase, hall, and entrance to the library and print gallery at Welbeck Abbey was exhibited at the Royal Academy of 1897. We give this week Mr. Leonard Stokes' designs for buildings in connection with the new street from Holborn to the Strand; a criticism will be found in our issue for October 31st last. We have now reproduced the whole eight designs sent in.

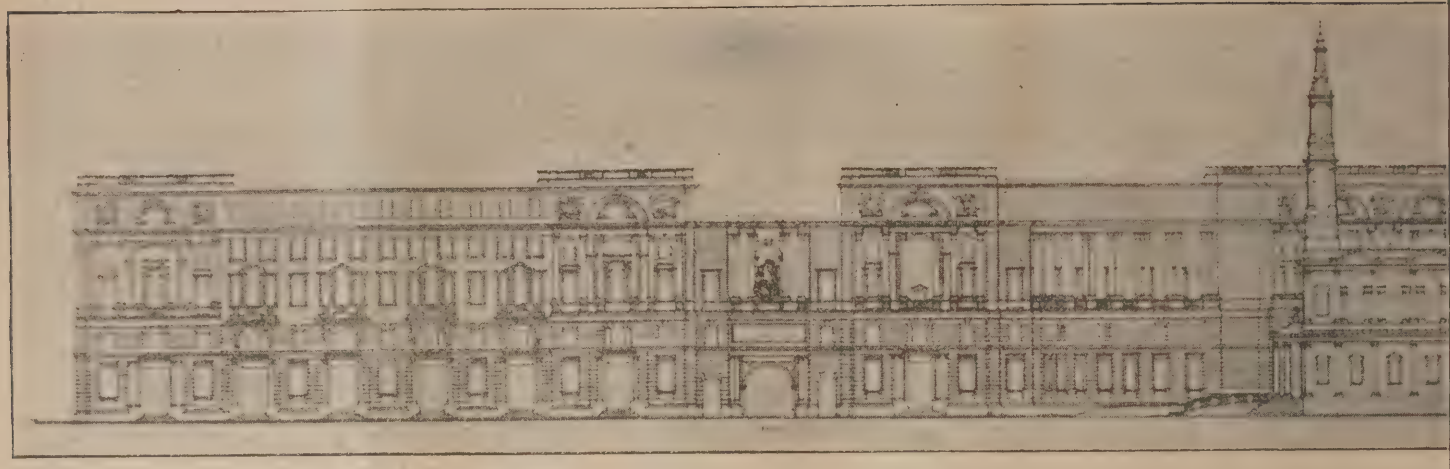
TIMBER ROOF AT BEAULIEU ABBEY, HANTS.

Ruskin and Morris. A WRITER in the "Review of the Week," in dealing with the principles of architecture, says that the one thing essential to remember, the one thing we are, alas! most readily disposed to forget, is that we are northerners, and, therefore, whatever else our architecture may be, this much at least it must be, of the north, northern, neither Indian, nor Grecian, nor Italian. Whatsoever beauties or appropriateness each one of these styles can boast in its own native place and clime, all are alike unsuited to the exigencies of our climate and the genius of our people. The two greatest prophets of art in our days, John Ruskin and William Morris, gave utterance to these primary principles with no vague or faltering language; Ruskin on ethical, Morris on scientific grounds. And, whereas, for all his eloquence, Ruskin failed to persuade the modern Englishman to abjure a particular mode which he assured him was corrupt and Pagan, Morris, on the other hand, appealed to a wide circle in emphasising the structural limitations of the Classic styles at a period when either was pure and distinct, and the sham construction of the combined Græco-Roman. Morris was never weary of insisting that, of all known forms of architecture, Gothic was the only one that possessed and exhibited a truly organic life and continuity of growth. Notwithstanding, both Morris and his master Ruskin were inconsistent in their practice. The latter arbitrarily fixed the perfection of Gothic as somewhere in the thirteenth century, and that preferably in Venice. Morris himself would have fixed the fourteenth century as the culminating period of English Gothic. So dismayed altogether was he by the deplorable manifestations of the "Gothic revival" that he came to accept a most pessimistic view of the prospects of architecture.

The Council and the Institute. THE Council of the Royal Institute of British Architects are of opinion that the suggested removal of the landing which now divides the flight of steps leading up to the portico of St. Martin's Church would be very detrimental to the appearance of the west front of the building. They say that "owing to the fall in the ground from north to south, the lower steps are of necessity broken off where they merge in the ground line. An unsymmetrical base of this kind to a symmetrical portico would have a distinctly bad architectural effect, but by the ingenious device of dividing the flight of steps in the middle, a perfectly symmetrical base of seven unbroken steps is provided for the colonnade, while the lower steps, which must terminate unsymmetrically, are separated from the design of the building, and do not form part of it." The Council feel, therefore, that nothing short of actual necessity could justify the removal of the landing or platform, while from the personal observation of its members and reliable information received, they are fully assured that no such necessity exists. In the event of the widening of the public footpath ever becoming necessary, they have no doubt the suggested setting back of the western steps is the least objectionable means of effecting the purpose. But even if, on account of such necessity, the landing be omitted from the steps in front of the portico, they strongly recommend that it should still be retained on the south side, where it would be useful in helping to preserve somewhat of a symmetrical appearance to the base of the portico. While considering the question of the appearance of this portico, they beg leave to suggest whether it would not be possible to remove the cast-iron railings now fixed at the top of the steps and between the columns, "as they constitute a serious disfigurement to the building."

Ancient Buildings in the Levant. A CORRESPONDENT of the "Times," writing from Jerusalem, complains of the wholesale destruction of historical monuments which is permitted by the Turkish Government. He says that two years ago a singularly interesting historical treasure was found in Jerusalem, the Cufic inscription at the entrance of the small mosque of Omar, once standing within the arcaded porch of Constantine's Basilica of the Holy Sepulchre, and dating from the seventh century. It was cut on a stone of the original Roman building and therefore *in situ*. On being found it was voted a mystery, because the small mosque of Omar was rebuilt on a quite different site after the Crusades, and this fact is unknown to modern natives of Jerusalem. However, to please various parties the old stone was torn from its position, and the inscription was sawn off and sent to Constantinople for better investigation. Its present fate is unknown. The interesting and well-preserved Church of St. Jeremiah, of the thirteenth century, at Abu Gosh, near Jerusalem, has been presented to the French Government, and a proposed "restoration" is now on foot. A friend, returning from a ride on the other side of Jordan, gave the "Times" correspondent a deplorable account of what is happening to the hitherto marvellously preserved cities of the Decapolis. The colonies recently planted in that region have selected the most famous cities for the purpose of turning them into stone quarries. Gerash (Gerasa) is filled with a Mahomedan colony which is provided with carts (a very modern innovation in the Levant), and the work of destruction is proceeding in a methodical manner. The famous "street of columns" is disappearing before the picks of the settlers and the columns are being broken up for building material. The curious circular colonnade at one end of the city is not yet touched. At Amman many of the well-preserved Roman monuments have disappeared during the past year. The great theatre is now nearly gone, and the carved stonework of the temples and other public buildings is being treated in the style of the unfortunate remains at Famagusta; it is being defaced, or rather refaced, with new dressing before being re-used to build the squalid huts of modern days. Cæsarea and Sebaste are examples of what has been done during the past ten years in the way of destruction, but the same system is now being carried out on a truly colossal scale all round the Levant. It would be difficult to enumerate the cities, towns, castles, and isolated monuments which are vanishing with the nineteenth century.

Timber Roof, Beaulieu Abbey. THE illustration on this page represents the timber roof at Beaulieu Abbey, in the New Forest, formerly a Cistercian monastery, pulled down in Henry the Eighth's time to build Hurst and Colshot Castles on the Solent. The roof is of solid oak beams. It is said that the room was intended for the working monks of the monastic colony, the best part being reserved for the guests. Now it is only a lumber-room, and the interior decorations, if any, have disappeared. The roof is a fine study for antiquarians and those interested in ancient architecture. We are indebted to Mr. G. K. Pearce for our illustration.



Italy's Art Treasures.—The second artistic law suit with regard to the sale of a bronze bust by Benvenuto Cellini to a firm of London art dealers has ended much in the same way as the recent suit with regard to the exportation of the Chigi Botticelli. Sanguinetti, who bought the bust from the Altoviti family, and the banker Pardo, who assisted him in selling it and smuggling it abroad, have been sentenced to pay a fine of £5,600 each and costs.

Law Cases.

Soft Bricks: A Successful Counterclaim.—The case of *Geall* v. *Docwra and Son* was recently heard before Judge Martineau at Chichester County Court. Mr. W. H. Geall, brickmaker, of Bersted, sued Messrs. Thomas Docwra and Son, contractors for the construction of the new reservoir for the Bognor Water Company, for £33 6s. 9d., balance of account due for bricks supplied on contract. Plaintiff's account was disputed on the ground that many of the bricks were not up to sample—some because they were soft and others because they were mis-shapen. Defendants on their part put in a counterclaim for £13 12s., made up as follows:—£3 12s. for extra labour in assorting and rejecting soft bricks, and £10 for dealing with mis-shapen bricks. Plaintiff's contention was that he had reasonably fulfilled the conditions of his contract, and had endeavoured to meet the defendants' objections in every possible way. Previous to the action coming into court the defendants had made a tender of £20 to the plaintiff, which was not accepted. The £20 had been paid into court. His Honour decided that the defendants had established their counterclaim, and gave judgment for the defendants with costs.

A Matter of Fixtures.—In the Court of Appeal last week the case of *Monti* v. *Barnes* was heard. This was an appeal of the plaintiff from a judgment of Mr. Justice Bigham, and raised the question whether certain articles at Long Walk House, Windsor, were fixtures, and passed with the house. It appeared that in 1890 Mr. P. St. L. Grenfell was the owner of Long Walk House, and he mortgaged it to Lady Ross. In 1893 the present defendant, Miss Barnes, became mortgagee in fee of the premises by a transfer to her by Lady Ross of the mortgage security of 1890. In 1893 Mr. Grenfell sold the equity of redemption to the plaintiff, Mr. P. Monti, and in March, 1898, the defendant foreclosed the mortgage, and became owner in fee of the premises. After the first mortgage was effected, and prior to its transfer to Miss Barnes, Mr. Grenfell had made great decorative improvements in the house, and it was with regard to certain articles then put on the premises that the original action was brought. They consisted of what is known as a "fitment" in one of the dressing-rooms, a large mirror in the drawing-room, and 11 dog-grates. These articles were claimed by the plaintiff on leaving the house, but the claim was resisted by the defendant on the ground that they were affixed to the freehold, and had become her property as mortgagee. Mr. Justice Bigham held that the articles were put into the house not for a mere temporary purpose but to improve the inheritance, and therefore became part of the house, and passed to the mortgagee. He consequently gave judgment for the defendant. Hence the present appeal. Their lordships were unanimously of opinion that the learned judge had come to a right conclusion, and they dismissed the appeal, with costs.

Penalty for Breaches of Building By-laws.—At Birkenhead Borough Police Court, Douglas L. Cleland recently attended to answer six summonses preferred against him by the Corporation for breaches of the building by-laws. The summonses were all in reference to a workshop and store being erected in New Chester Road, Birkenhead. The Corporation passed the plans for its erection on February 15th, 1900, but on July 15th a building inspector found several defects in the building. One wall was not built thick enough, being 4½in. thick instead of 14in. The drains were not ventilated sufficiently, and there were no damp-courses or footings to the walls. Summonses were also issued on account of the defendant having continued the offences when advised not to do so. Defendant's solicitor contended that as the Act applied to a manufactory or warehouse the case fell to the ground. The place was a joiner's workshop, and not a manufactory or anything else. His client was a very busy man, and had left the work to a foreman, which accounted for the negligence in some way. —The chairman said that the magistrates had given the case very careful consideration, and had borne in mind the fact that the building was a workshop and not a dwelling-house. If it had been a dwelling-house the penalty would have been greater. But they would like to point out that if every person carrying on building operations in Birkenhead were allowed to have concessions made to him, as had been done in this case, the surveyor's department would require a very much larger staff. The magistrates did not think that the defence offered was entirely satisfactory. The chairman then imposed fines in each of the cases, the total penalty amounting to £14 19s., or, in default, four months' imprisonment in all.

Builders on Councils: An Important Case.—The case of *Walsh* v. *Grimsley* was heard last Thursday before Mr. Justice Bigham in the Queen's Bench Division of the High Court of Justice. This was an action brought by Mr. John Gorden Walsh, a solicitor, of Bicester, against Mr. Thomas Grimsley, of the Causeway, Bicester, for an injunction restraining the defendant from acting and from continuing to act until April 15th, 1901, as chairman of and as a member of the Urban District Council of Bicester. It appeared that in June last, whilst the defendant was a member and chairman of the Council, the Council invited tenders for certain repairs to a house called the surveyor's house, and a tender by Mr. F. E. Grimsley and Mr. C. H. Grimsley, sons of the defendant, was accepted, and the work done in accordance with the tender. The defendant is a builder and general contractor for works, and the plaintiff's case was that, although the tender was made in the names of the sons (who occupied some clay, brick, tile, and pipe works at Bicester), the contract, even if the defendant's sons were the sole joint occupiers of the clay, brick, tile, and pipe works separately from the defendant, was carried out in such a manner and was so intermingled with the business of the defendant as to be for all purposes inseparable from his business, and that the defendant was necessarily concerned in the contract. The case for the defendant was that, although he did not dispute that he supplied his sons with the labour and materials at cost price, he made no profit and was not in any way interested in the contract. Mr. Justice Bigham, in giving judgment, said that he was of opinion that the plaintiff was interested in the matter and therefore entitled to the relief he claimed under section 46 of the Local Government Act, 1894, if the circumstances justified it. In April, 1898, the auditor of the district council surcharged the accounts of the council with an item in respect of work which had been done by the defendant for the council. Upon an appeal to the Local Government Board, they directed that the account should be paid upon the ground that the penalty was not that the contractor should have his account struck out and not paid, but that he should cease to be a member of the council. It was clear that upon that occasion the defendant did something which brought him within the provisions of this very salutary section. Because of that decision, and in order that work of that kind might at all events be secured to his family, the defendant and his two sons founded another firm. The defendant paid the rent and rates of the premises and the wages of the persons employed there. The two sons then started what they called a brickfield. They were not builders except in the sense that they made bricks. The father paid the rent, wages, rates and taxes, and the clerk who kept the one single book. In his opinion the business was the father's. He did not believe that the sons made any such payments to the defendant as they alleged. In his opinion the sons' firm was simply a blind or means to avoid the operation of the section. Further, in his opinion, the contract of June, 1900, was the father's, and he came within the meaning and mischief of the section. The defendant was not only concerned in the contract, but was the actual contractor, and he was therefore disqualified from remaining a member of the council. He wished to say that his experience showed that there were upon local boards far too many of this class of men—builders and persons who were likely to be interested in work required to be done for the local body. They were tempted to enter into contracts with which they ought to have nothing to do. He therefore made a declaration that the defendant was no longer entitled to sit as a member of the council.

LONDON COUNTY COUNCIL.

The Steps of St. Martin's—Land Registry Office—Electric Traction—Lighting the Embankment—County Hall—Housing—New Workhouse at Grove Park.

AT last week's meeting of the Council the Improvements Committee brought up a further report with reference to the proposed widening of St. Martin's Place by the alteration of the steps in front of St. Martin's Church. When the matter was before the Council on October 23rd on the recommendation that a contribution should be given towards the improvement, it was referred back to the Committee with instructions to take expert opinion as to the architectural effect of the proposed alteration. The opinion of the Royal Institute of British Architects was accordingly taken, and they reported that the alterations would be detrimental to the appearance of the west front of the church. If an improvement was urgently required they suggested certain modifications, and the Committee now recommended the Council to make a contribution of £270, one-third of the cost of the reconstruction of the steps in front of the church in such a way as to increase the width of the footway on the eastern side of St. Martin's Place to about 9ft., on condition that the council of the City of Westminster should agree to retain the platform on the steps on the southern side of the church, this being considered the least objectionable method of providing for a widening of the thoroughfare at this point. The Committee did not feel themselves able to advise the Council to arrange for the removal of the cast-iron railings from the top of the steps, as suggested by the Royal Institute. Mr. Shaw-Lefevre pointed out that the architects reported that the alteration would seriously affect the architectural effect of the church, and that nothing short of actual necessity could justify the removal of the landing or platform. They also stated that, should the widening of the footway ever become necessary, they had no doubt that the suggested setting back of the western steps was the least objectionable means of effecting the purpose, but they strongly recommended that the landing on the south side should be retained. That was the scheme adopted by the Committee, but in his opinion it was still objectionable and would interfere with the architectural features of the church. He thought that, as there was a strong professional feeling against the alteration, it would be better for the Council to take no part in it, and moved as an amendment that, in view of the report of the Royal Institute of British Architects, the Council was not prepared to take the responsibility of sanctioning the alteration by contributing any part of the cost. The Hon. W. Peel, M.P., said he would be no party to the mutilation of this beautiful church. It was wholly unnecessary for the Council to assist in damaging the church for the sake of merely adding 2ft. 6in. to the footway. When they asked the opinion of a body like the Royal Institute they should be led by its report. Mr Burns, M.P., was not prepared to help to make the Council a zereba behind which the Westminster Council could shelter itself from the artistic and æsthetic views which London architects would undoubtedly bring to bear upon it for tampering with this church. He suggested that one of the wealthy parishioners, such as Mr. Astor, should give the vicar of St. Martin's £10,000 with which to engage a competent architect under whose guidance they could underpin the whole church, including the portico, put it on a sliding gantry, remove it 40ft. back, and give it an alignment with Duncannon Street. In that way alone could the widening of St. Martin's Place be carried out without injuring the church. He asked the Council to preserve itself from a suggested act

of vandalism.—The amendment was carried by a large majority.

Mr. John Burns, M.P., asked whether it was true that the Government proposed to erect the Land Registry Office in Lincoln's Inn Fields 80ft. high, and projecting 12ft. in advance of the other buildings. Mr. Goddard Clarke said that was so. The Building Act Committee had sent a letter to the Office of Works, and a reply had been received that afternoon. It stated that the building was to be constructed in accordance with the expressed views of certain authorities, but Mr. Akers-Douglas shared to a great extent the views of the Council and would cause a further communication to be addressed to the Council on the subject. Mr. Radford asked whether it was not true that the Act authorising the construction of the building expressly exempted the structure from the operation of the London Building Act. Mr. Goddard Clarke said that was so.

Upon the recommendation of the Highways Committee, the Council approved the system of electrical traction devised by Dr. Kennedy for the tramways between Westminster and Tooting, Kennington Park Road and Blackfriars, and St. George's Circus and Waterloo Road. Mr. Benn, chairman of the committee, said that the cost was estimated at £15,000 a mile single track, and £30,000 double track.

The Council accepted the tender of the Gilbert Arc-Lamp Company for the supply of the arc lamps to be used for the lighting of the Embankment and Westminster Bridge.

The Special Committee on New Offices recommended the Council to pass the following resolution:—"That in the opinion of the Council it is not expedient that a site on the crescent island to be formed in connection with the Holborn to the Strand improvement should be reserved for the erection of new offices for the Council." Mr. Shaw-Lefevre moved the adoption of the recommendation, and pointed out that the Committee had arrived at their conclusion chiefly on the score of the cost of the site. If the residue of the crescent island after providing for the reinstatements were utilised for a new county hall, the cost of the site would be £2,400,000. That figure was four or five times as much as the estimated cost of the Westminster Aquarium site or a site on the Westminster improvement area. Besides, a site in the Strand was further removed from the public departments and the Houses of Parliament than would probably be found desirable. Mr. Goulding, M.P., moved to add to the recommendation, "but that the Committee bring up a report without delay as to what site they do recommend for the erection of a county hall and offices." Mr. Horniman seconded the amendment, which was adopted. The recommendation as amended was carried unanimously.

Mr. Waterlow presented the report of the Housing of the Working Classes Committee, which showed a nett deficiency of £1,157 on the year's working. There was a surplus of £505 on the Council's own buildings, and a loss of £1,663 in regard to those which they had been compelled to erect on the sites secured by the Metropolitan Board of Works. This deficiency was less than last year, when the total was £2,392. There was a serious loss on their cottages and small houses in South-East London. There was a deficiency on the Boundary Street Central Laundry of £1,074; indeed, it had been a terrible failure. The Council now had open fifty-four dwellings, with a provision for 10,686 persons, at a cost of £653,000. They also had nearly ready, at a cost of £303,000, dwellings to accommodate 5,666 persons. Other plans prepared would accommodate 14,853 persons, at a cost of £863 513. Altogether they would have accommodation for about 30,000 people, at a cost of £1,819,000. The report was received and adopted.

Upon the recommendation of the Finance Committee it was agreed to lend the Guardians of the Greenwich Union £150,000 on the annuity system for the erection, fitting, and furnishing of a new workhouse at Grove Park.

The Society for the Encouragement of the Fine Arts held its annual meeting last Friday. Messrs. Charles Keyser, Alfred Gilbert, G. C. Haité, and Dr. J. S. Phene were elected vice-presidents.

Keystones.

The Interior of Woburn Parish Church, Buckinghamshire, which dates from about 1200 A.D., has been extensively restored.

The Parish Church of Old Basford, Nottingham, was completely destroyed by fire last week. The church was an ancient one, and was undergoing restoration.

Hampton Court Palace is to be given another attraction by the re-erection of thirteen wrought-iron gates which formerly stood at intervals between the Palace private gardens and the river. The gates, which are fine specimens of wrought-iron work, have been exhibited in museums throughout the country.

Carpenters' Technical Schools.—Lord Reay, G.C.S.I., Chairman of the late School Board and President of University College, has consented to distribute the prizes won by students of the Carpenters' Technical Schools at Great Titchfield Street, and by students in the Company's classes at King's College, &c., on Thursday next, the 6th inst.

The Death is announced of Mr. Henry Currey at the age of 80 years. He was an Associate of the Institute of Civil Engineers, a Fellow of the Surveyors' Institution, and Fellow of the Royal Institute of British Architects. He was the architect of St. Thomas's Hospital, on the Albert Embankment, and the hotel at London Bridge railway terminus.

Glover's Island, which lies in the Thames at the foot of Richmond Hill, has been purchased by Mr. Max Waechter, Deputy-Lieutenant of the county of Surrey, and has been presented by him as a free gift to the Corporation of Richmond, subject to the present unsightly buildings being pulled down, and no others erected except a suitable keeper's lodge, to the banks being maintained, and to the island being planted.

Housing of the Working Classes.—The council of the Sanitary Institute have addressed a letter to the members of her Majesty's Government, in which they express a hope that the Government will find time to bring forward in Parliament without delay a satisfactory measure of reform on the lines indicated in the resolutions passed at a conference on the housing of the working classes convened by the Institute and reported on page 11 of our issue for August 8th.

A new Church Room at Petersham, has been erected on the Butehouse Estate, immediately below the Thompson Walk, in Richmond Park. On the estate a new church is also being built, which will be after the style of the first Canterbury Cathedral. The old parish church, which is of exceptional interest owing to its monuments of Vancouver and others, will still be retained and used. The public generally will derive benefit from these gifts, as it was proposed to turn the land into a building estate, which would have completely spoilt the view from Richmond Hill.

The Edinburgh Architectural Association held its inaugural meeting last week. Mr. Henry F. Kerr, A.R.I.B.A., gave a paper on "A Visit to Melrose Abbey," illustrated by lime-light views. He outlined the history of the Abbey from its foundation by David I. in 1136, when a colony of Cistercian monks was established on the silver banks of the Tweed from Rievaulx, in Yorkshire. Like all the Border abbeys and churches, its buildings suffered many devastations, most notably by Edward I., Edward II., Richard II., and the Earl of Hertford. But, though damaged and pillaged by the Kings of England, it was honoured and fostered by the Kings of Scotland. Founded by David I., gifted with fines and forfeited lands by Robert the Bruce, and further enriched by Alexander II., it reached the zenith of its fame in the thirteenth century. Mr. Kerr then described in detail the existing remains, and referred to its old-world associations, the wondrous rise to prosperity and worldly greatness, the terrible retribution of ruin for laxity and evil, all telling their own tale.

The Ancient Tower of Clare Parish Church, Suffolk, has been re-opened after restoration.

A new Hall and Recreation Rooms at Cambuslang is to be erected at a cost of £1,400. The architect is Mr. A. Lindsay-Miller, of Glasgow.

Devon and Exeter Architectural Society.—A paper on "The Architecture and Sculpture of Greece" was read before this society last week by Mr. C. J. Tait, A.R.I.B.A. (president).

94 Park Street, N.W.—In the paragraph accompanying the illustration of this shop front on page 329 of last week's issue the word "this" was erroneously printed for "tiles," in the sentence "and that this should be used below the shop front."

A Shakespearean Find.—In laying drains on the site of Shakespeare's last residence, at New Place, Stratford-on-Avon, some workmen a day or two ago came upon the old foundations. A wall 3ft. 6in. thick, and a very solidly-built well were the chief traces of the "Great House," as it was called, which dates from the reign of Henry VII.

The practice of the late Charles Henry Driver, F.R.I.B.A., A.I.C.E., of 17 Victoria Street, Westminster, is to be carried on by his eldest son, Mr. C. H. Driver, in conjunction with Mr. Stanley Barrett, architect, under the style or firm of Barrett and Driver. The practice will be transferred to Mr. Barrett's office, 53 Blomfield Road, Maida Vale, W.

A new Church at New Brighton, Liverpool has been opened. The building is of brick, and provides accommodation for 400 persons. The cost has been £4,600. The premises consecrated form only a portion of the complete design, but are considered to be sufficient for present needs. When the front portion of the church is erected additional accommodation will be provided for 500 persons.

Berths Wanted for C.I.V.'s.—The "Daily Express" offers to act as agent between unemployed C.I.V.'s and employers, and applications have been received from one who has had six years' experience in the office of an architect and surveyor, while another would like a situation as assistant to an architect. Any of our readers having such openings should communicate with the "Daily Express," Tudor Street, E.C.

Cardiff By-laws.—At a meeting of the public works committee of the Cardiff Corporation, amongst the plans brought forward were those of the proposed new Seamen's Hospital, to be erected near the shore at the docks end of the town. Mr. E. W. M. Corbett, the architect, sent a letter with the plans, and drew attention to the fact that in the plans he had designed there were several things that were breaches of the by-laws, but he hoped that the committee would consider all the circumstances, and allow them to pass. It was held that the by-laws could not be altered by the committee, although the opinion was expressed that the by-laws pressed very hard in many cases.

The British Archæological Association held its second meeting of the session on November 21st, Mr. C. H. Compton, in the chair. The hon. editorial secretary (Rev. H. J. D. Astley) read an interesting résumé of the proceedings of the recent Congress at Leicester. Mr. Astley also read some "Notes on the Mound Dwellings of Auchingaish," by Mr. W. A. Donnelly. The locality of these mounds is the north-west corner of Dumbartonshire, in the picturesque and mountainous belt which runs between Loch Lomond and the Gareloch on the Auchingaish, one of the highest tributaries of the Fruin Water. The mounds are all more or less circular in shape, standing about 5ft. high at the highest, but more often not more than 3ft. 6in. above the level of the natural hillside, and present a remarkable similarity to the homes of the beaver. Excavations made in some of them disclosed the existence of boulder-built walls, rude and strong, each mound having a narrow doorway, with the jambs invariably in their original position, but the lintels displaced, and in two instances lying on the doorstep. The general characteristics of these mounds suggest the idea of their having been the homes of an early pigmy race.

COMPLETE LIST OF CONTRACTS OPEN.

DATE OF DELIVERY.	WORK TO BE EXECUTED.	FOR WHOM.	FROM WHOM FORMS OF TENDER MAY BE OBTAINED.
	BUILDING.		
Dec. 7	Holyhead—Post Office	H.M. Office of Works	Office of Works, Storey's Gate, S.W.
" 7	Pembroke Dock—Barracks	War Department	Royal Engineer Office, London Road, Pembroke Dock.
" 7	Hayes, Middlesex—Groundwork	British Electric Transformer Manufacturing Company, Limited	Company's Office, Woodfield Road, Harrow Road, W.

Trade and Craft.

Lifts.

One of the most notable features of the nineteenth century is the universal application of the principles of mechanics for saving labour, reducing cost, and accelerating production. The development of engineering has been the keynote of all manufacture and in each of the numerous branches a marvellous change has been effected. Not the least is the improvement which has been, and is still being, made in the design and construction of lifting machinery of all kinds, an improvement which has resulted in the production of remarkably efficient appliances. In the front rank of modern manufacturers of lifts and hoisting machinery Messrs. R. Waygood and Company, Limited, of Falmouth Road, Great Dover Street, London, S.E., occupy a prominent position. To keep pace with the increasing demand for lifts and cranes of all sorts they have found it necessary to revise their catalogue, which is now divided into three parts, dealing respectively with hand lifts and cranes, lifts and hoists driven by steam and belt power, and hydraulic lifts and machinery, especially passenger lifts. The hand-power lifts include varieties for use in warehouses and manufactories, for passengers, food, coal, and a number of other purposes, while the belt-driven lifts are specially suitable for factories and works where engine power is used for driving the machines used in the various operations of manufacture. Hydraulic lifts are being increasingly employed. They are of two kinds—direct-acting and suspended, the former consisting of a cage borne directly on the top of a ram which slightly exceeds in length the distance the lift has to rise, the latter having a ram of shorter stroke and a multiplying cylinder round which pass the wire ropes suspending the cage. Direct-acting lifts are essentially the safest, the strain on the machinery being always in compression, but with suspended lifts there is a saving of expense when the height of travel is considerable; moreover, in some cases it would be inexpedient to excavate a deep well to receive the long ram cylinder. Messrs. Waygood have devoted considerable time and money to the design of a safety apparatus for lifts, and they have achieved success. During the Liverpool Exhibition of 1887 a test was made with their apparatus, twelve men getting into a cage suspended by a hemp rope; at a given signal the rope was cut, but the grips immediately came into action, the cage having fallen 1¼in. only. The cage is now suspended from four steel ropes, and it has been found, after careful experiment, that the gear is certain to act if any of the ropes fail; as an extra safeguard a fifth rope is provided which bears no weight unless *all* the other ropes part. It is impossible here to notice the many other improvements which Messrs. Waygood have introduced, but special attention should be given to their electric lifts, which can be made to work more economically than any others. For those requiring any kind of lifting machinery we cannot do better than refer them to this firm.

New Companies.

Bright Buildings, Limited.

This company was registered on November 10th with a capital of £4,800 in £100 shares to acquire certain land fronting to Hill Street and John Bright Street, Birmingham, and to carry on the business of builders, contractors, decorators, builders' merchants, architects, surveyors, agents, &c. The first directors (to number not less than two nor more than five) are F. Taylor, A. J. Bolus and G. Kenwick. Registered office: 33 New Hall Street, Birmingham.

Imperial Electrical Supplies Company, Limited.

This company was registered on November 5th with a capital of £50,000 in £1 shares to adopt and carry into effect an agreement made by this company with G. Bargate, G. S. Hertslet, H. W. Knott, E. P. Harvey and J. L. Bell; and, generally, to carry on in all its branches the businesses of electrical and general engineers. The first directors (of whom there shall be not less than two nor more than seven) are G. Bargate, G. S. Hertslet, H. W. Knott and E. P. Harvey.

Horsehay Company, Limited.

This company was registered on November 6th with a capital of £100,000 in £10 shares to adopt and carry into effect an agreement made by this company with H. C. and A. Simpson for the acquisition of the business of engineers, &c., as carried on at Horsehay Works, Horsehay, Salop, by the Horsehay Company, and, generally, to carry on in all or any of their branches the businesses of iron and steel roof, girder, and bridge makers, engineers, and metal founders, smelters, cable manufacturers, hardware dealers, &c. The first directors (of whom there shall be not less than three nor more than seven) are H. C. Simpson (chairman), A. Simpson, H. R. G. Bayley and J. Simpson, jun.

Electric Lighting Boards (British Manufacturing Company), Limited.

This company was registered on November 8th with a capital of £75,000 in £1 shares to adopt and carry into effect an agreement made by this company with the Electric Lighting Boards, Limited, to acquire the benefit of certain existing inventions relating to luminous advertisements and electric-lighting boards, and to manufacture and deal in and with any articles used in connection with the same. The first directors (of whom there shall be not less than three nor more than seven) are to be elected by the signatories—W. G. Gadsden, A. Tibbits, H. L. Pring, W. Brittan, J. W. Strickland, E. Newroy and A. H. Lister.

E. R. Saile and Co., Limited.

This company was registered on November 14th with a capital of £300 in £1 shares to carry on at Kettering or elsewhere the business of shop, bar and office fitters, counter makers, decorators, sign makers, electricians, gas fitters, ironfounders, &c.

French Electric Lighting Boards, Limited.

This company was registered on November 15th with a capital of £4,000 in £1 shares to acquire from E. O. Sachs the benefit of certain existing inventions relating to electric lighting boards for luminous advertisements or otherwise. The first directors (to number not less than two nor more than five) are to be appointed by the subscribers. Registered office: 7 Pall Mall, S.W.

Deans, Limited.

This company was registered on November 9th with a capital of £500 in £1 shares to acquire the business carried on at Alsager, Cheshire, by Dean Brothers, and to carry on the business of timber and wood cutters, splitters, and dealers, sawyers, firewood manufacturers and merchants, &c. The first directors (to number not less than two nor more than five) are to be appointed by the subscribers.

Perfect Light Company, Limited.

This company was registered on November 13th with a capital of £25,000 in £1 shares to adopt an agreement with the Scott, Snell Phillips Syndicate, Limited, and M. Lachman, and to carry on the business of electricians, manufacturers of electrical and lighting apparatus and lamps of all kinds, &c. The first directors (to number not less than three nor more than five) are C. S. Snell, C. W. Phillips and M. Lachman.

Armstrong and Co. (Birmingham), Limited.

This company was registered on November 14th with a capital of £5,000 in £1 shares to acquire the business carried on by H. R. Hill, J. H. Rogers and R. M. Hughes at Peel Buildings, Lower Temple Street, Birmingham, as Armstrong and Co., and to carry on the business of builders' merchants, brick, tile and pipe manufacturers, &c. The first directors (to number not less than three nor more than five) are H. R. Hill, R. M. Hughes and J. H. Rogers. Registered office: 128 Colmore Row, Birmingham.

Della Robbia Pottery and Marble Co., Ltd.

This company was registered on November 13th with a capital of £3,500 in £1 shares (1,750 preference) to adopt an agreement with the Della Robbia Pottery, Limited, and its liquidator, and an agreement with H. S. Rathbone and E. de Caluwe, and to carry on, at Birkenhead, Liverpool, and elsewhere, the business of pottery and ornamental marble manufacturers, contractors for decorative works for architectural, ecclesiastical, domestic and other purposes, &c. Harold S. Rathbone and Emile de Caluwe are the managers.

TENDERS.

Information from accredited sources should be sent to "The Editor." Results of tenders cannot be accepted unless they contain the name of the Architect or Surveyor for the Work.

BROMSGROVE.—For the erection of isolation hospital at Hill Top, Bromsgrove, for the Bromsgrove, Droitwitch, and Redditch Joint Boards. Mr. Henry T. Hare, London, and Herbert R. Lloyd, Birmingham, joint architects:—

Barnsley & Son	£12,388 0 0	J. Dallow	£11,195 0 0
C. Bryant	12,245 0 0	Dorse & Co.	11,125 0 0
T. Rowbotham	12,120 0 0	W. Hopkins	10,800 0 0
Hurley & Son	11,963 0 0	W. & J. Webb	10,559 0 0
Sapcote & Son	11,837 0 0	W. Bishop	10,445 0 0
Huino & Son	11,600 0 0	J. Tilt	10,400 0 0
D. Panter	11,506 12 0	Harvey Gibbs	10,350 0 0
Guest & Son	11,500 0 0	J. & A. Brazier, Broomsgrove *	10,080 0 0
Moffat & Son	11,370 0 0	Gowing & Ingram	9,993 0 0
T. Broad	11,825 0 0	* Accepted.	
Smith & Pitts	11,277 0 0		

CHADWELL HEATH.—For the erection of villa residence in Whalebone Grove, for Mr. A. Tatham. Mr. J. M. H. Gladwell, architect, 34 Lawrence Road, Bow:—

A. Webb	£1,595	J. R. Holliday	£1,275
G. R. Reid	1,500	Finegan & Co. *	1,148
G. W. Death	1,350	* Accepted.	

DEVONPORT.—For the erection of electricity works, buildings, &c., East Stonehouse, exclusive of chimney and flues. Mr. Charles Furniss, Borough Electrical Engineer, Devonport. Quantities by Mr. H. Gray Robins, 55-56 Chancery Lane, London:—

May	£7,969	Wakeham Bros.	£5,906
Hortop	7,391	Blake	5,831
Skinner	6,821	Lapthorn	5,709
Hatcham & Co.	6,710	A. N. Coles, Plymouth	5,433
R. H. B. Heal	6,140	* Accepted.	

DONCASTER.—For the execution of private street works, Church Street, &c., Butcher Street, and Cross Butcher Street, Thurnscoe, for the Rural District Council. Mr. J. R. Dodds, Civil Engineer, 19 Baxter Gate, Doncaster:—

W. Johnson	£2,633 0 0	B. Roberts, Retford*	£3,040 16 10
R. T. Hodgson	2,307 9 6	W. H. Cliffe	2,021 17 10
Jones Bros.	2,214 19 2	J. Holmes	1,823 0 0
W. Chapman	2,207 7 9	Yardley, Dransfield and Taylor†	904 6 7
F. Eyre	2,194 15 10		

* Accepted. † Church Street only.
[Engineer's estimate, £2,283 5s. 8d.]

DUNDALK.—For additions, &c., to old Grammar School buildings and conversion into free library. Mr. Wm. Beck, architect, Dundalk:—

McAdorey	£1,198 0 0	McGuinness, Dundalk*	£1,041 18 6
Wynne	1,193 0 0	* Accepted.	
Parks	1,171 16 10		

ILFORD, Essex.—For erection of Methodist Free Church, Ilford Lane, for the trustees. Mr. F. W. Dixon, architect, Trevelyan Buildings, Manchester. Quantities prepared by Mr. A. Goodchild, 81 Finsbury Pavement, London, E.C.:—

F. & E. Davey	£6,095	F. Willmott	£5,225
G. H. Hosking	5,827	Battley, Sons & Holness	5,167
Castle & Son	5,800	J. W. Jerram	5,123
G. Sharp	5,756	F. J. Coxhead	5,027
S. J. Scott	5,695	W. J. Maddison, Clarkson Street, Canning Town, E.*	4,926
Shelbourne & Co.	5,249	* Provisionally accepted.	

NEWTON ABBOT.—For new girls' school at Highweek, for the Highweek School Board. Messrs. J. W. Rowell & Sons, architects, Newton Abbot. Quantities by Mr. Vincent Cattermole Brown, of Paignton:—

W. Gibson	£2,840 0	H. Drew	£2,180 0
F. J. Stokes	2,524 0	R. F. Yeo	2,160 0
W. A. Goss	2,398 0	F. Stacey, Newton Abbot*	2,051 19
L. Bearne	2,315 0	* Accepted.	
Geo. Hicks	2,300 0		

RADLETT, Herts.—For proposed residence. Messrs. S. Doddimeade Edmunds, architect, St. Albans and London:—

J. Verdon	£1,900 0 0	Boff Bros.	£1,230 0 0
C. H. Taylor	1,372 14 8	G. Wiggs	1,140 0 0
W. King	1,310 0 0	* Accepted.	

SLIGO.—For the erection of chapel in the Asylum grounds for the Committee of Management of Sligo District Lunatic Asylum. Messrs. Sir Thomas Deane & Son, architects, 15 Ely Place, Dublin:—

J. & P. Good	£5,200	John Clarence	£4,600
Michael Gallagher	5,200	D. McLynn, Sligo*	4,275
		* Accepted.	

COMING EVENTS.

Wednesday, December 5.

BUILDERS' FOREMEN AND CLERKS OF WORKS' INSTITUTION.—Ordinary meeting at 8 p.m.

INSTITUTE OF SANITARY ENGINEERS.—Meetings of General Purposes and Finance Committee at 3.30 p.m., and Election Committee at 5 p.m.

GEOLOGICAL SOCIETY OF LONDON.—Meeting at 8 p.m.

SURVEYORS' INSTITUTION.—Meeting of Elections Committee at 4 p.m.

RUSKIN SOCIETY OF BIRMINGHAM.—The Very Rev. G. W. Kitchin, D.D., on "Ruskin in the Old Oxford Days," 8 p.m.

NORTHERN ARCHITECTURAL ASSOCIATION.—Council meeting and Students' Evening.

EDINBURGH ARCHITECTURAL SOCIETY.—Mr. Thomas Hume, F.I.S.E, on "Effect of Heat and Cold on Plumber's Work, and how to Prevent Damage Therefrom."

SOCIETY OF ARTS.—Prof. H. S. Hele-Shaw, LL.D., F.R.S., on "Road Traction," 8 p.m.

BRITISH ARCHÆOLOGICAL ASSOCIATION.—Mr. T. Cann Hughes, M.A., on "A Ramble in South Devon," 8 p.m.

ROYAL ARCHÆOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—Mr. P. M. Johnston on "Wall Paintings, &c, at Hardham Church, Sussex, and at St. Mary's, Guildford," 4 p.m.

Thursday, December 6.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—Prof. R. H. Smith, Wh. Sc., A.M.I.C.E., M.I.M.E., on "Valve Gears and Valve Diagrams," 8 p.m.

SOCIETY OF ANTIQUARIES OF LONDON.—Meeting at 8.30 p.m.

CHEMICAL SOCIETY.—Meeting at 8 p.m.

Telegraphic Address: "Astra, Stoke-on-Trent." Telephone No. 2097.

By Special Appointment.

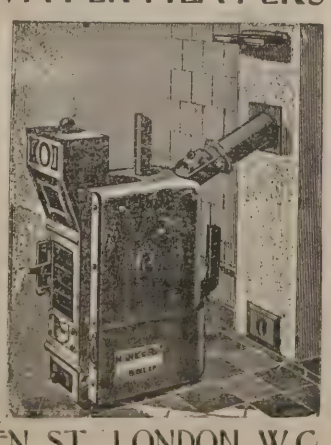
MINTON'S

All kinds of TILE WORK, FAIENCE, or MOSAIC, estimated for. Special Designs for Pavements, Halls, Wall Linings, and Fireplaces sent free.

London House and Show Rooms:
50 CONDUIT ST., REGENT ST., W.

By Special Appointment.

TILES



Large Works specially designed and estimated cost furnished. Illustrated Catalogue sent Free on application.

An Architectural Causerie.

First-floor Shops. SIR FREDERICK BRAMWELL'S reply to his critics is interesting, though one still feels that his scheme would not be a success architecturally. When the question was first raised Mr. Frederick Harrison pointed out that the London County Council could not build on the immense area of the new street from Holborn to the Strand, and he asked how it could impose the task of erecting an upper footway on purchasers and lessees. Doubtless the first-floor shops would add to the rental value per length of frontage, but we are inclined to believe that the requirement in question would hamper very considerably the disposal of the land. To meet the case of different buildings being erected at different times, leaving great gaps between them, Sir Frederick Bramwell ingeniously proposes that the Council should provide, within a certain time after the letting of the first plot, a temporary footway of girders at the first-floor level. He assures us that it was never intended to dispense with pillars, which he considered essential to the picturesque architectural effect, and his bridges across the main thoroughfare were not a necessary part of his scheme, but simply possibilities arising out of it. "I do not see any way," he says, "by which I could further advocate this mode of construction short of inducing some architect of position to associate himself with me in the preparation of an artistic design—of which I do not profess myself to be capable (although I would answer for stability)—with the hope that such a design might find its place among the architectural drawings in the Academy next May. But to do this would involve my devoting a more considerable portion of my time to the matter than I can afford." Certainly this is a fitting conclusion to Sir Frederick's proposal.

A New Factor. SINCE its opening in June last, the Central London Railway has received unstinted praise and liberal patronage—which it well merits; but now that the novelty of the undertaking is wearing off, a serious complaint has been made against it. When, in 1891, the parliamentary committee was investigating the scheme, expert evidence was given to the effect that as the railway line would be 60ft. below the ground no noise or vibration could possibly be heard or felt in the adjacent houses. The fact, however, is otherwise, as the following two cases prove. The first is that of a house in the West End, 28yds. from the high road under which the electric railway runs. Every time a train passes the whole house is shaken to its foundations, the window sashes rattle in their frames, and ornaments in the rooms are set in vibration. The second case concerns a house about 23yds. from the road: here the same vibration is felt, and there is very little quiet except between the hours of 1 a.m. and 5 a.m. It is not surprising that cracks have appeared. There seems to be no cure for this state of affairs except to construct the tunnels still lower, but without doubt attention will be drawn to the fact when the Bills for the numerous new "tubes" are brought before the present session of Parliament. It need hardly be pointed out that the vibration referred to depreciates the value of the houses affected, as nobody desires to live in a building which is in a state of almost constant tremor. Nevertheless, so long as the railway is worked in the manner authorised by Parliament, those who live along the route may have their repose broken or their houses shaken down, but they will not be entitled to compensation or damages.

Our Narrow Pavements. THE visitor from the country or from abroad marvels at the narrowness of the London streets. Here and there, indeed, within the vast circle of houses wide streets may be found, but even these have very narrow side-pavements. Those of Regent Street are not wide enough for the throngs who lounge and stroll through it; in Bond Street it is difficult for three people to pass at some points; Piccadilly from the Circus to the Green Park is little better; the City, the busiest place in the world, is full of narrow lanes and alleys, and the inconvenience of all this to the public is great and increasing. Strange to say, the new streets, made after so many years of discussion and opposition, are not remarkable for width, though better than those they superseded; and, more curious still, they are not straight: Shaftesbury Avenue and the miserable circus of indeterminate outline where it is intersected by Charing Cross Road are dreadful examples of civic failure. A vast new approach to Westminster is now opened up by the widening of Parliament Street, but the footways are quite inadequate. The question arises, too, of tree planting in so wide a street: it will be dreary without it, but it is very doubtful if anything will be done. The immense masses of white stone which will be built along its sides would be greatly improved in architectural appearance by rising over trees and foliage, for which there is ample room. No great street—for the Embankment is not a popular thoroughfare, and therefore not a case in point—in London has yet been so treated. It would probably be found necessary, in view of the traffic, to protect the trees by a little "parking" enclosed by dwarf walls and balustrades with openings at frequent intervals. An arrangement of the kind may be seen in Westbourne Terrace. If we wish the enormous London of the future to be comfortable our footways must be wide enough for throngs of people strolling for pleasure as well as for those hastening on business.

GATEWAY TO CHRIST'S HOSPITAL, LONDON.—DRAWN BY J. HUTCHINGS.

ANCIENT LONDON.

BY J. HUTCHINGS, A.R.I.B.A.

THE City of London has been most unjustly described as lacking in the picturesque element, a charge thoughtlessly made, and one which only the Philistine or casual observer would dare to maintain. Be this as it may, no one can deny that much of the quaintness of London streets is due to those relics of a past age that remain clustered here and there, but which unhappily are fast disappearing. Many of them appear as solitary survivors, who, having so far weathered the storms of time, now stand out conspicuously amongst a host of moderns; in a measure, they seem to have outlived their own generation.

Doubtless it is in harmony with the laws of the universe that the old should give place to the new, and that progress, or at least change, should proceed unimpeded by the sentiment that attaches itself to all ancient things. Nevertheless, it is occasionally worth while to study pleasing examples of the architecture of the past, and to compare them with the productions of to-day, with a view to gauging the value of modern art.

Many of the originals of the accompanying illustrations have disappeared, and those not already doomed to destruction protract a precarious and uncertain existence.

Those familiar with the Fleet Street of a few years ago, can recall without effort the appearance of the old plaster-fronted houses that recently adjoined St. Dunstan's Church, and lent quite an old-world aspect to that busy and "up-to-date" thoroughfare. To the student of English literature they formed a link with the days of the coffee-houses and the illustrious band of essayists and poets that made famous the England of a century ago. They appeared an appropriate background for the scenes described by Mr. Spectator, and but a little imagination was required to picture the burly and ungainly figure of Dr. Johnson waddling through Temple Bar, past these old houses on the one side and the palace of Henry VIII. and the Temple on the other, on his way to take wine with Addison and Steel, Goldsmith and Boswell, at the Mitre Tavern. Before the suppression of the Fleet marriages, the houses were thriving business premises, and doubtless played their part in those irregular proceedings. Their weather-beaten fronts have looked down upon many a stormy fray in the street below, when the populace, goaded by oppression and heavy taxation, made a fanatical raid upon the lawyers of the Temple, the supposed authors of all their woes; or it might be that the "'prentices," in answer to a call for aid, rushed out to rescue some members of their fraternity in trouble with the civic authorities.

Aubrey informs us in his "Lives" that Michael Drayton the poet "lived at the Bay window house, next the east end of St. Dunstan's Church in Fleet Street."

Previous to the rebuilding of St. Dunstan's the churchyard was covered by houses abutting against the fabric itself in quite continental style. It appears that Smethwick, the original printer of some of Shakespeare's plays, "lived in one of the shops in St. Dunstan's churchyard, that under the clock." And in the same locality "Marrot published the first edition of Walton's Angler."

Old St. Dunstan's Church was noted for a projecting clock, embellished with two figures of Hercules, which struck the hours, and was considered to be one of the sights of the metropolis. The Hercules Tavern derived its name from these effigies.

Hard by St. Paul's an old landmark still exists in Panyer Alley, though, owing to its unobtrusive position in the front of a building facing a narrow lane, it is known to few. It was embodied in the new structure erected some years ago, and was thus fortunately preserved *in situ*. The monument consists of a stone panel bearing sculptured upon the surface the figure of a child seated upon a pannier, with the following legend inscribed below:—

WHEN Y HAVE SOUGHT
THE CITY ROUND
YET STILL THIS IS
THE HIGHEST GROUND
AUGUST THE 27
—1688—

The mediæval architects frequently placed their cathedrals on the top of rising ground, and so it happens that St. Paul's occupies a position that could not be bettered in all London.

The gateway to Christ's Hospital, until recently the Bluecoat Boys' School, is an exceptionally good example of brick architecture, simply treated and in excellent preservation. Even the Ionic capitals and bases are of the same material; they are very good specimens of plastic work. The attachment of the modern Tudor addition behind, rising above the Renaissance pediment, is a pointed illustration of the irony of fate, for the original builders regarded the Gothic style as utterly barbarous and doomed for all time, little suspecting that their own example of seeking inspiration for a new development by a revival of past forms would be repeated, with consequences even more fatal to steady progress than those which immediately attended their own aberrations. The figure of King Edward VI., the founder, clad in the costume prescribed for the inmates, is the only evidence now left to remind us of the time when the hatless boys, clad in long coats and yellow stockings, were seen flitting about Newgate Street or playing football in the schoolyard.

A few hundred paces distant, bordering upon the slums of West Smithfield and quite out of the regular beat of the visitor and sightseer, stands a fine fragment of what was once a splendid monastic establishment. The old priory church of St. Bartholomew is the finest example of the late Norman period in London, and ranks with the very best specimens of its class in the kingdom. Rahere, the founder, was a gay courtier-cleric of the reign of King Henry I., who, falling sick whilst on a pilgrimage to Rome, repented of his former dissolute life and vowed to erect on his recovery a hospital for the poor in the neighbourhood of London. These good resolutions, as was not uncommon in those days, were reinforced by supernatural visions, and in pursuance of his scheme he secured a grant of land at West Smithfield, and there laid the foundation-stone of his great undertaking.

The nave and transepts of the old church have disappeared; the stones of the conventual buildings and the cloister formed convenient material for the erection of the houses that arose on the monastery grounds after the Dissolution, and so have disappeared; only the eastern limb of the church, the four great arches of the crossing, with fragments of the Lady chapel, have survived to the present day, together with the neighbouring hospital of St. Bartholomew, an institution which still continues its career of usefulness unimpaired by the lapse of centuries, though of the first building no traces remain. Rahere was buried in the sanctuary which occupied many of the latter years of his life in building, and the position of his resting-place is marked by a superb Perpendicular tomb, raised by a fifteenth-century prior, on which lies a wooden effigy of the founder; the latter is older than the tomb. Opposite this monument, inserted in the triforium gallery, is a sixteenth-century oriel window bearing the rebus of the builder, Prior Bolton. This window was doubtless erected for the convenience of watching the shrine, on which a lamp was kept perpetually burning.

The architecture of the church is of late Norman character, massive, dignified, well proportioned, and the details combine the boldness of the earlier work with much of the elegance, variety and playfulness that distinguished in so eminent a degree the first Pointed style. The tracery of the clerestory windows is modern.

The apse is a restoration by Mr. Aston Webb, a sixteenth-century prior having destroyed the original in constructing a square termination embellished by a great traceried window in

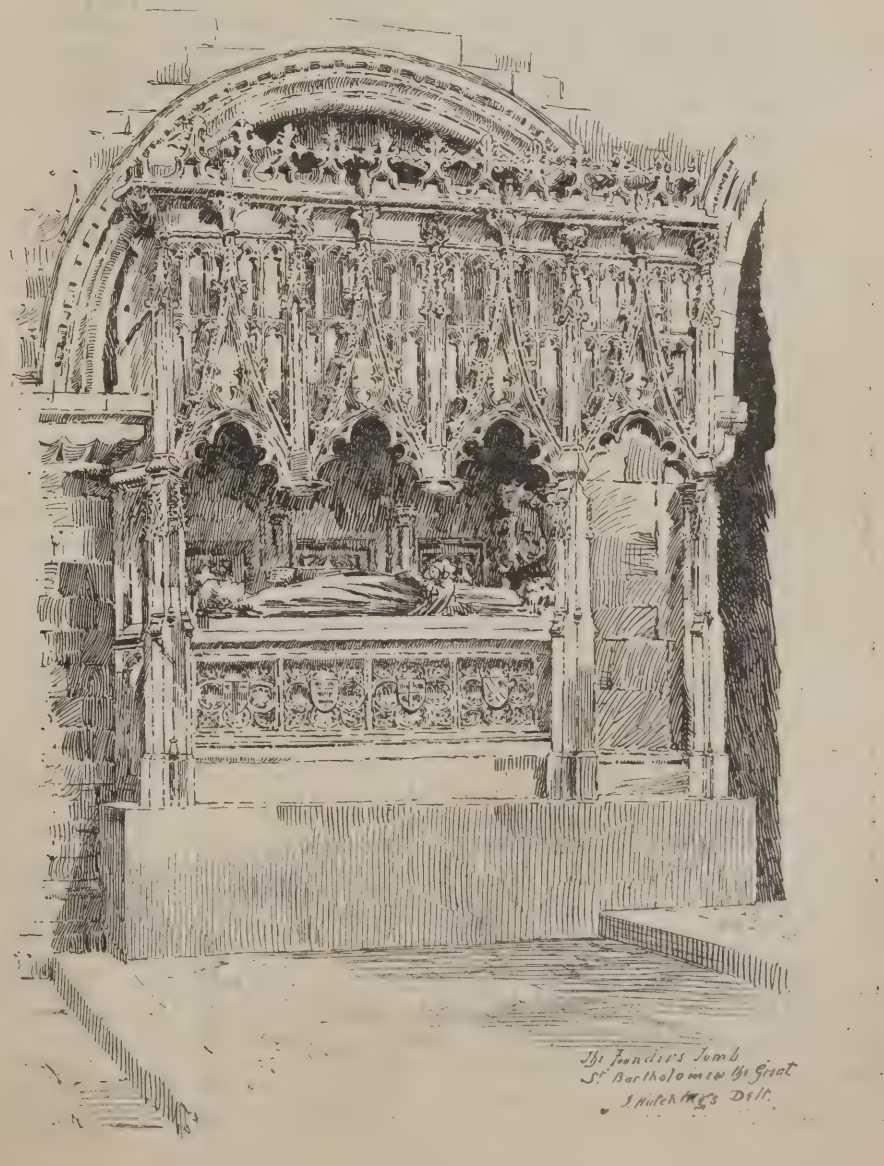
Old Houses
Fleet Street.
J. Hutchings

accordance with the national tradition of his time. The same architect (Mr. Webb) practically rebuilt the south transept, and in all he has done to this great church he has dealt reverently with its crumbling walls, abstaining from pulling down anything that would stand for years to come, re-using, wherever possible, old fragments that were unearthed in excavations; and in the new work he has exhibited a modest individuality, upon which the old has been allowed to exercise a due restraint, instead of imitating with mathematical exactness ancient forms with the vain object of deceiving the eye, a course tempting by its ease, by its sureness to attain a certain degree of harmony, and one which would have been followed by a less able man. As it is, the happy manner in which the old contrasts, and at the same time accords, with the new establishes Mr. Webb's reputation as a master builder, and must win the respect due to those who, while showing a proper reverence for past, successfully demonstrate the value of new ideals.

A great fair was held at West Smithfield, called Bartholomew Fair, from which the monks, in the palmy days of the monastery, derived no small pecuniary advantage. This institution survived the latter, and later writers tell us much about the doings at these great merry-makings. Pepys informs us how he went to Bartholomew Fair and saw "the mare that tells money and many things to admiration." On another occasion he describes the puppet-shows which used to be so popular, and of which he speaks with great approbation.

It is a truism that we know least those objects amongst which we dwell, and it were curious to enquire how many City men are acquainted with the superb interior of St. Stephen's, Walbrook, an edifice they pass a score of times a day, and drive their bargains upon its very threshold. This church presents so unprepossessing an exterior that it can scarcely be a matter of wonderment that few care to become more intimately acquainted with it. But the interior, in point of architectural effect, is second to none of Wren's designs, and is so utterly different from the ordinary basilica plan that it has been a matter of surprise to many writers that this type of sanctuary, so admirably adapted to meet the exigencies of modern worship, should have been neglected by succeeding architects. Perhaps lesser men shirked the difficulties of a problem that taxed all the resources of a Sir Christopher Wren; in any case they adopted the fatally easy course of repeating badly what had been better done before, a habit that is almost as prevalent to-day with the majority of church architects, and one which has filled our land with spurious Gothic edifices — slavish copies — as true in point of detail to the original models as Chambers' much-sneered-at Somerset House is faithful to the rules of Vitruvius, but ten times more soulless, inasmuch as the whole spirit of Gothic work consists of variety, individuality even eccentricity, of detail, constant change, and a development that is appreciable in a single building. Chain the soaring spirit of Gothic, fetter its imagination, apply what was evolved to meet the requirements of centuries ago to the needs of the present, and the result is a melancholy fiasco. It were better, far better, to return to plain unadorned utilitarianism, and, if need be, decorate our portals with a death's-head, rather than with the dead weeds of an extinct architecture. St. Bartholomew's was the result of collectivism in architecture; St. Stephen's was the work of an individual: the one utilised all the ability and invention possessed by each particular craftsman engaged; the other merely demanded mechanical finish, and a faithful copy of the details. The latter method, then in its infancy, has in the eyes of the political economist arrived at the highest state of efficiency, and by dividing men into two hostile camps—thinkers and mechanics—has resulted in a vast cheapening of production. In the eyes of the humanitarian it is held responsible for all the physical ills that beset the brainworker, by depriving him of healthy exercise and specialising his thinking faculty at the sacrifice of all else; it is held responsible for robbing the other class, and by far the larger, of all interest in their labour, and has made them either animals or machines.

The plan of the church is an oblong, consisting of a large central dome supported on columns. But the ability shown in overcoming the extraordinary difficulties of construction, the exactness of the proportions, the clever manner in which the light is introduced, and the exquisite effect of the whole, are evident even to the uneducated, and cannot fail to impress the beholder with delight.



(To be concluded.)

RECENT PRACTICE IN SEWAGE DISPOSAL.

IN the course of a paper on this subject, read before the Society of Engineers on December 3rd, Mr. Henry C. H. Shenton referred to the older methods of sewage disposal, pointing out that, until recently, failures of sewage works, constructed under all the older systems, had been notorious. As an example he quoted the failure of the combined chemical treatment, filtration and land irrigation system at Sutton in 1895, two years after the works were constructed. Passing on to the modern system of bacterial purification he stated that it consisted of the resolution of impurities into inoffensive materials by the agency of micro-organisms. He pointed out that changes, formerly considered chemical, were really due to the action of bacteria, and that the bacteria necessary for the purification of sewage already existed in it.

Turning to practical work the author remarked that for the bacterial treatment of sewage there were two methods: (1) that in which sewage passed through a tank where anaërobic organisms produced liquefaction of solids and putrefaction as a step towards purification, the effluent being then purified on bacteria beds; and (2) the system in which no tank was used, the crude sewage being purified on bacteria beds only.

In describing the practical construction and working of the bacteria bed the author said it consisted of a water-tight tank, containing furnace clinker or other durable material likely to form a home for bacteria, into which sewage could be run, and in which it could be held to bring it into contact with bacteria. The effluent from this bed, after it had stood a short time, would be greatly purified, and could be again

treated on second or third contact beds. In describing the septic tank the author said it was of practical use in getting rid of sludge, but he pointed out that the storage of putrid sewage in bulk was not an ideal arrangement. The septic tank is an air-tight chamber with trapped inlet and outlet, from which liquid only should be discharged, owing to the fact that solids must either float or sink.

While pointing out the many admirable results obtained at works constructed by the Septic Tank Syndicate, the author drew attention to the failure of a septic tank constructed by the Leicester Corporation. He then showed that a septic tank need not necessarily be air-tight, as open and closed tanks had produced identical results. He also stated that gas generated in the Exeter septic tank was used for lighting purposes and for generating steam by which an 8-h.p. engine was driven.

He mentioned the folly of allowing road grit to go on to bacteria beds, and said that first-contact beds were generally much overworked. He suggested a possible improvement to obviate this, which consisted of an alteration in the construction of the first bed. He also said that automatic working was essential for success, and, in conclusion, he pointed out that the new system was equally applicable for the largest city or the smallest cottage. The paper was illustrated by diagrams and lime-light views of works.

FORM OF BUILDING CONTRACT.

THE PROPOSED AMENDMENTS.

CONSIDERABLE attention has been drawn to the proposed amendments of the "Form of Agreement and Schedule of Conditions for Building Contracts." The matter was discussed at the meeting of the Royal Institute of British Architects held on December 3rd, when much dissatisfaction was expressed with regard to clause 32 as amended. The Council are now reconsidering this clause. The amended clauses as proposed are set out below.

1. The works shall be carried out in accordance with the directions, and to the reasonable satisfaction of the architect, in accordance with the said drawings and specification, and in accordance with such further drawings, details, and instructions in explanation of the same as may from time to time be given by the architect. If the work shown on any such further drawings or details, or necessary to comply with any such instructions, directions, or explanations, be, in the opinion of the contractor, in excess of that comprised in the contract, he shall, before proceeding with such work, give notice in writing to this effect to the architect. In the event of the architect and contractor failing to agree as to whether or not there is any excess, and of the architect deciding that the contractor is to carry out the said work, the contractor shall accordingly do so, and the question whether or not there is any excess, and if so the amount thereof, shall, failing agreement, be settled by the arbitrator as provided in clause 32, and the contractor shall be paid accordingly. The contract drawings and specification shall remain in the custody of the architect, and shall be produced by him at his office as and when required by the employer or by the contractor.

12. The contractor shall, when authorised by the architect, or as provided by clause 5, vary by way of extra or omission from the drawings or specification; such authorisation is to be sufficiently proved by any writing or drawing given by the architect, or by any subsequent written approval by him. No claim for an extra shall be allowed unless it shall have been executed under the provisions of clause 5, or by the authority of the architect as herein mentioned. Any such extra is hereinafter referred to as an authorised extra.

17. [The sole difference between the amended and the original clause is the omission in the former of the words "or other person" in the sentence beginning "Should any defective work have been done or material supplied by any sub-contractor . . ."]

20. All specialists, merchants, tradesmen, or others executing any work, or supplying any goods for which prime-cost prices or provisional sums are included in the specification, who may at any time be nominated, selected, or approved by the architect, are hereby declared to be sub-contractors employed by the contractor; but no such sub-contractor shall be employed upon the works against whom the contractor shall make what the architect considers reasonable objection, or who will not enter into a contract with the contractor upon terms and conditions consistent with those in this contract, and securing the due performance and maintenance of the work supplied or executed by such sub-contractor, and indemnifying the contractor against any claims arising out of the misuse, by the sub-contractor or his workmen, of any scaffold erected or plant employed by the contractor, or that may be made against the contractor in consequence of any act, omission, or default of the sub-contractor, his servants or agents, and against any liability under the Workmen's Compensation Act, 1897, or any amendment thereof.

21. The contractor shall be responsible for all structural and decorative damage to property, and for injury caused by the works or workmen to persons, animals, or things, and shall hold the employer harmless in respect thereof, and also in respect of any claim made under the Workmen's Compensation Act, 1897, or any amendment thereof, by any person in the employ of the contractor. He shall also be responsible for all injuries caused to the buildings, the subject of this contract, by frost or other inclemency of weather, and shall reinstate all damage caused by the same, and thoroughly complete the whole of the works.

28. The provisional sums mentioned in the specification for materials to be supplied or for work to be performed by special artists or tradesmen, or for other works or fittings to the building, shall be paid and expended at such times and in such amounts and to and in favour of such persons as the architect shall direct, and sums so expended shall be payable by the contractor without discount or deduction, or (without prejudice to any rights of the contractor existing under the contract referred to in clause No. 20) by the employer to the said artists or tradesmen. The value of works which are executed by the contractor in respect of provisional sums, or in additional works shall be ascertained as provided by clause 13. At the settlement of the accounts the amount paid by the contractor to the said artists or tradesmen, and the said value of such works executed by the contractor, shall be set against all such provisional sums or any sum provided for additional works, and the balance, after allowing *pro rata* for the contractor's profits at the rates contained in the contractor's original estimate, shall be added to or deducted from the contract sum, provided that in estimating the amounts paid as last herein provided no deductions shall be made by or on behalf of the employer in respect of any damages paid by the sub contractor to the contractor, the intention being that the contractor, and not the employer, shall have the benefit of any such damages.

29. The contractor shall permit the execution of work by any other artists or tradesmen who may be engaged by the employer.

32. Provided always that in case any dispute or difference shall arise between the employer or the architect on his behalf and the contractor, either during the progress of the works or after the determination, abandonment, or breach of the contract, as to the construction of the contract, or as to any matter or thing arising thereunder (except as to the matters left to the sole discretion of the architect under clauses 4, 9, and 19, and the exercise by him under clause 18 of the right to have any work opened up), or as to any objection by the contractor to any certificate, finding, decision, requisition, or opinion of the architect, or to the withholding or failure by the architect to give the same, then either party shall forthwith give to the other notice of such dispute or difference, and such dispute or difference shall be and is hereby referred to the arbitration and final decision of or, in the event of his death, or unwillingness, or inability to act, of or, in the event of his death or unwillingness or inability to act, of a person to be appointed on the request of either party by the President for the time being of the Royal Institute of British Architects, and the award of such arbitrator shall be final and binding on the parties. The arbitrator shall have power to determine all such matters in dispute except as aforesaid which shall be submitted to him, and of which notice shall have been given as aforesaid. The works shall not be stopped pending such reference excepting by the direction in writing or award of the arbitrator. If either party desires to have such dispute or difference determined forthwith, he shall give written notice to that effect to the other party, and the arbitrator shall, with the assent in writing of the other party, proceed with the arbitration. In the event of the other party failing within days of such notice to give to the other his assent in writing to the immediate determination of such dispute or difference, the arbitrator shall, after written notice to the non-assenting party of a time and place of hearing, decide whether such dispute or difference shall be immediately determined or whether such determination shall await the completion or alleged completion of the works, and the same shall be determined at such time or times as the arbitrator shall decide. If in any such reference the arbitrator shall be of opinion that either party has been unreasonable or vexatious or dilatory either in invoking or insisting upon reference or in the mode of its conduct, or that injury from delay or otherwise has been occasioned thereby to the other, he may by his award indemnify the latter in respect of such injury. Upon every or any such reference the costs of and incidental to the reference and award respectively shall be in the discretion of the arbitrator, who may determine the amount thereof, or direct the same to be taxed as between solicitor and client, or as between party and party, and shall direct by whom, and to whom, and in what manner the same shall be borne and paid. This submission shall be deemed to be a submission to arbitration within the meaning of the Arbitration Act, 1889.

Surveying and Sanitary Notes.

The Institute of Sanitary Engineers.—At a meeting of the Election Committee held on the 5th inst., the following were elected:—*Fellow:* T. E. Fellows, Willenhall. *Member:* A. W. Pelling, London. *Associate:* A. E. Kinder, Blackpool.

Heaton Park, the seat of the Earl of Wilton, and the last of the great private estates in the Manchester district, has been sold to a London syndicate for building purposes, the price paid being £240,000. Previous attempts to dispose of the park with a reserve of a quarter of a million sterling had failed, and suggestions had been made that it should be purchased by the Corporation of Manchester as a public park.

Plumber's Work.—The Edinburgh Architectural Society held a meeting on December 5th, when a lecture was delivered on "The Effects of Heat and Cold on Plumber Work, and How to Prevent Damage therefrom," by Mr. Thomas Hume, F.I.S.E. The subject was discussed at some length, in relation to the different metals now used in the execution of plumber work, some of which were entirely dissimilar in their nature to lead, the metal originally pertaining to plumber work, and up to a period about fifty years ago almost exclusively used in that trade. The effect of changes of temperature on these different metals was very striking, and by the extensive introduction of hot-water systems for domestic use these effects had become much more obvious and destructive. Careful study of these effects, which in their nature were irresistible, was therefore needful in order to avoid their destructive influence or reduce it to a minimum. Reference was made to the damaging effects of frost on exposed water-pipes and the need of ample means of protection being used, especially in the case of pipes connected with pressure boilers.

Correspondence.

"Render unto Cæsar."

To the Editor of THE BUILDERS' JOURNAL.

SIR,—For many years I have taken your paper regularly and can bear testimony to its high qualities, literary and artistic, but I must say that I cannot agree with "J. B.," who writes under the above title in your issue for November 14th. I cannot agree with his recognition of the "Cæsar" in "the architect who cannot draw"; neither do I like the patronising way in which he speaks of the "draughtsman-architect" as compared with "the architect who does not draw." Why "draughtsman" applied almost as a term of reproach to the one, as if he were nothing else, and the full-blown title "architect" to the man who has not taken the trouble to learn the first part of the profession he lives by?

"J. B." cites a particular case of "an architect who is a truly great designer of an almost monumental dignity," and brings in the draughtsman-architect who did his work for him and is now, I rejoice to hear, "in a practice of his own, a draughtsman-architect among the best of them"; and then brings in the point that his successor is also a very clever fellow, and "the work which comes from the office still maintains its excellence, and more than that, its subtle individuality."

Quite so. I have seen the same thing done in many many instances, and "J. B.'s" architect who cannot draw would be utterly lacking in worldly wisdom if he were not to replace talent by equal, or even greater, talent, provided he could obtain it; in fact, it is a matter of life and death to such a man to do so.

As "J. B." has evidently taken up a brief for the architects who cannot draw, perhaps he will enlighten some of us, who would like to know, how these gentlemen convey their subtle ideas and individualities into the brains of their assistants.

How could such a design, say, as the Scott Monument in Edinburgh have been conveyed from the brain of Kemp into the brain and fingers of another had Kemp been unable to draw? Fortunately, Kemp did not need the assistance of another, and there is no question as to any ghost in that instance.

In the long ago, when I was serving my indentures, a story went the round of a then great Scottish artist that a lady asked him out of curiosity how it was his pictures were always so successful, sold so readily, and at such high prices. Being somewhat of a wag, he replied, "Oh! I get so-and-so (naming a famous landscape-painter) to do my landscapes, so-and-so (naming a great animal painter) to put in the animals, so-and-so (a great figure painter) to put in my figures, and so-and-so (whose skies were always the best part of his pictures) to put in my skies." "And where do you come in, Mr. B.?" said the astonished lady. "Oh!" he replied, "I sign the pictures and take the high prices."

No, Mr. "J. B.," your "Cæsar" is a sham and a fraud and not by any means the genuine article; in fact, he is not an architect at all; he is a tradesman with capital in hand and buys and sells like any other tradesman—and has his name attached to his wares like the retail bootmaker or hatter has on the goods he gets from the various wholesale firms with whom he deals. But boots and hats soon wear out and no real harm is done, while architecture lasts longer and the monumental works which are carried out by the architect who could not draw go down to posterity as his own works, and the real architect is unknown.

"J. B." may say, then, why does the draughtsman-architect consent to do it, and become "a being who has sold himself for a few pounds a week?" Well, sir, as another of Mr. "J. B.'s" architects has it, "a man must live." It is the old story of Jacob and Esau over again. Jacob had what was necessary to Esau's existence, and Esau had to pay the price.

But there is a remedy for all this. Let the profession be put on a proper basis, like the legal or medical, and only men admitted who can pass its examinations on all necessary points; and in the meantime I would suggest that the merchant-architect should publicly couple the name of his helpmate with his own and divide the spoils with him, instead of considering that he ought to be satisfied with a weekly wage. Knowing there is always available talent to be had, I am afraid this last suggestion will not be so readily followed up as it ought to be, because the Jacob of to-day is so much like the old article that he will rob his brother in the present (legally, of course) as he did in the past.—Yours truly, I. Y.

SIR,—If your correspondent "I. Y." will kindly re-read my article he may find that the views therein expressed are, after all, not so greatly at variance with his own as he seems to suppose. It may be that something in the manner of the saying rather than in the matter of it is in the front rank of my offending. So, at least, I am inclined to guess. For, had my remarks, in stirring amongst his rooted convictions, struck against any of his bed-rock principles, surely he would have been able to deliver an attack of a less nebulous sort. And yet it is a right good sort of attack, too, in its way—its own "knock-me-down" way. Its very nebulousness is the "kopje" from whose cover he launches his missiles, his deadly "J.B.'s" (I declare, Mr. Editor, that if he had got in but one more "J. B." I should have surrendered unconditionally). But, fortunately, after firing his seventh round, he comes out on the open, and there one can see what he is made of.

He proposes a remedy—for what, one is not perfectly clear—but the remedy itself is simple, and the directions on the wrapper are explicit: Shake the bottle and take as directed: "Let the profession be put on a proper footing . . . and only men admitted who can pass their examinations on all necessary points." Aha! sits the wind in that quarter? And in case this should be too strong a dose to take all at once, or in order to allay impatience during its preparation, we have a gentle sedative offered us: "In the meantime I would suggest" (thus runs the prescription) "that the merchant-architect should publicly couple the name of his helpmate with his own and divide the spoils with him." A good idea! Oh, shades of Moloch. Five per cent., an excellent idea! Of course he should; but will he? Not, for sure, if he is only a "merchant-architect," or unless there are such material advantages in the arrangement as his merchant-eye would be the first to detect.

Now I protest I spoke not of any merchant-architect. I know the breed, and like it not. Nor will I admit the soft impeachment of having "taken up a brief for the architects who cannot draw"; but for those who *do* not draw—which is another matter. It is time someone did take up a brief for these good gentlemen (they are too busy to do it themselves, too busy, maybe, to care whether it is done or not); and why not I, if they will have me, or for want of a better? They make a broad target for muddy missiles. It is so easy to besmear them. There are so many hard names to fling at them. And how tempting a thing it

INTERIOR, ST. BARTHOLOMEW'S CHURCH, LONDON. DRAWN BY J. HUTCHINGS.

is to have at those who are successful! For we may as well admit the fact, the non-drawing architects are generally among the successful ones; it is their success that has robbed them of the leisue for drawing, and has forced them to become brain-workers alone. Again, suppose we do admit the cannots to a share of toleration. Why not? I do not see that even they need necessarily be all and altogether "merchant-architects."

The point is this: Can an architect (who does not command the full-blown title of draughtsman-architect, but is just, poor fellow, a plain architect) conceive a building root and branch, plan, mass, and detail, and then communicate his ideas all and whole to his draughtsman? If the latter is a man like-minded to himself, an architect like himself, though not for the moment *the* architect, can he do it? He can, he does, and his name is Legion beyond the one or two men I had in my mind when I wrote.

But when I am invited to describe how the thing is done, I really must kindly, but very firmly, decline. That were quite a large order. Indeed, that would be to attempt to lay bare the great psychological secret that makes all the difference between worthy success and worth without success; between the mind of the man who is fitted not only to be a good architect, but to make a great practice, and that of him who may be fitted to be a good architect, but—— It is a very big and unsurmountable But.—Yours truly, J. B.

Keystones.

A Block of Workmen's Dwellings in Lambeth has been erected in St. George's Road, on the Hayle's Estate, at a cost of £50,000.

A Proposed Infectious Diseases Hospital at Whickham formed the subject of a Local Government Board enquiry recently in regard to an application by the Whickham Urban District Council for sanction to borrow £3,250 for the purpose.

Mr. E. C. Howell, London, has been appointed chief clerk of the works in connection with the new municipal buildings and law courts at Cardiff. Mr. Howell has superintended the erection of some very important works, amongst them being the new Parliamentary buildings at Victoria, British Columbia.

Tom Hughes Memorial.—It is desired to raise a sum of £15,000 for the improvement and enlargement of the Working Men's College buildings in Great Ormond Street, and it is understood that the scheme is intended to form a memorial to the late Tom Hughes, who was so ardent a supporter of the college.

New Theatre for Greenock.—Greenock Dean of Guild Court recently passed the plans for a new circus and theatre of varieties for Greenock. The building will be situated in West Blackhall Street, only a few yards from Greenock Theatre Royal. It will seat two thousand persons, and can be utilised either as a circus or a music-hall.

A Y.M.C.A. building at Leicester has been erected, at a cost of over £30,000, opposite the Midland Railway station. It is four storeys high, and, with the exception of the shops on the ground floor, the whole of the premises will be devoted to the objects of the Young Men's Christian Association. In addition to the ordinary reading and recreation rooms, a hall and a large gymnasium are provided, as well as about thirty bedrooms.

Discovery of a fine Greek Statue.—A short time ago during some excavations at Pompeii a magnificent bronze statue of Grecian workmanship 4ft. high was brought to light. The discovery was made in the presence of Professor Orsi, director of the excavations of Syracuse. The statue, which strongly resembles the celebrated "Idolino degli Uffizi," of Florence, is estimated to be worth £20,000. It is in perfect preservation, and seems to have been designed to support a lamp in some villa outside the walls of Pompeii. It is the most important discovery made at Pompeii for the last thirty years.

New Sunday Schools at Rogerstone have been erected at a cost of £1,300. The architects were Messrs. Habershon, Fawckner and Groves.

The National Schools, Banbury, are being warmed and ventilated by means of Shorland's patent Manchester grates and special inlet panels, supplied by Messrs. E. H. Shorland and Brother, of Manchester.

Cripplegate Church Gateway.—In carrying out the improvements in Fore Street steps are to be taken to preserve this ancient landmark. The view of the north side of the church will, however, probably be obscured, because the Corporation of London is looking to the sale of the land to recoup itself for the heavy expenditure—£19,000—which the improvements involved.

The London and Middlesex Archæological Society held its first meeting of the present session at the London Institution, Finsbury Circus, E.C., recently. In the absence of the president (Dr. Freshfield) Mr. Deputy White presided. A lecture was delivered by Mr. H. W. Fincham on "An Antiquarian Ramble through Clerkenwell." The various places of interest were noticed, including Hicks Hall, Old Baptists' Head, St. Mary's Nunnery, St. James's Church, Red Bull Theatre, the two prisons, the New River Head, the tea gardens of the last century, Sadlers' Wells, London Spa, and Bagnigge Wells.

The Steps of St. Martin's.—All efforts to prevent the alteration to the steps of St. Martin's Church have been futile, for the City of Westminster Borough Council decided last Thursday to proceed with the work. Lord Doneraile moved as an amendment: "That the matter be referred back with a view of considering how the work could be carried out without altering the architectural character of the building, and that the contract be varied accordingly." Alderman Emden said the contract was entered into by the late St. Martin's Vestry, and if the work did not proceed they would have to compensate the contractors. On a show of hands the amendment was rejected by 24 votes to 23, and on a division by 28 to 24.

The Leeds School of Art and Technical School being in need of extra accommodation, a new building is to be erected upon a site in Vernon Street at the back of the present premises. The following Leeds architects have been invited to send in designs for competition, and all have accepted:—Messrs. Bedford and Kitson, Mr. W. Carby Hall, Messrs. Howdill and Howdill, Mr. F. Musto, Mr. A. E. Dixon, and Messrs. Perkin and Bulmer. Mr. W. H. Bidlake, of Birmingham, will act as assessor. The estimated cost of the new building is £10,000, some portion of which the public will be invited to contribute. This move on the part of Leeds does not stand alone, for Hull has entered into a scheme to provide a new School of Art at a cost of £17,000, and Birmingham, whose School of Art stands first in the country, has just added a branch building costing £6,602.

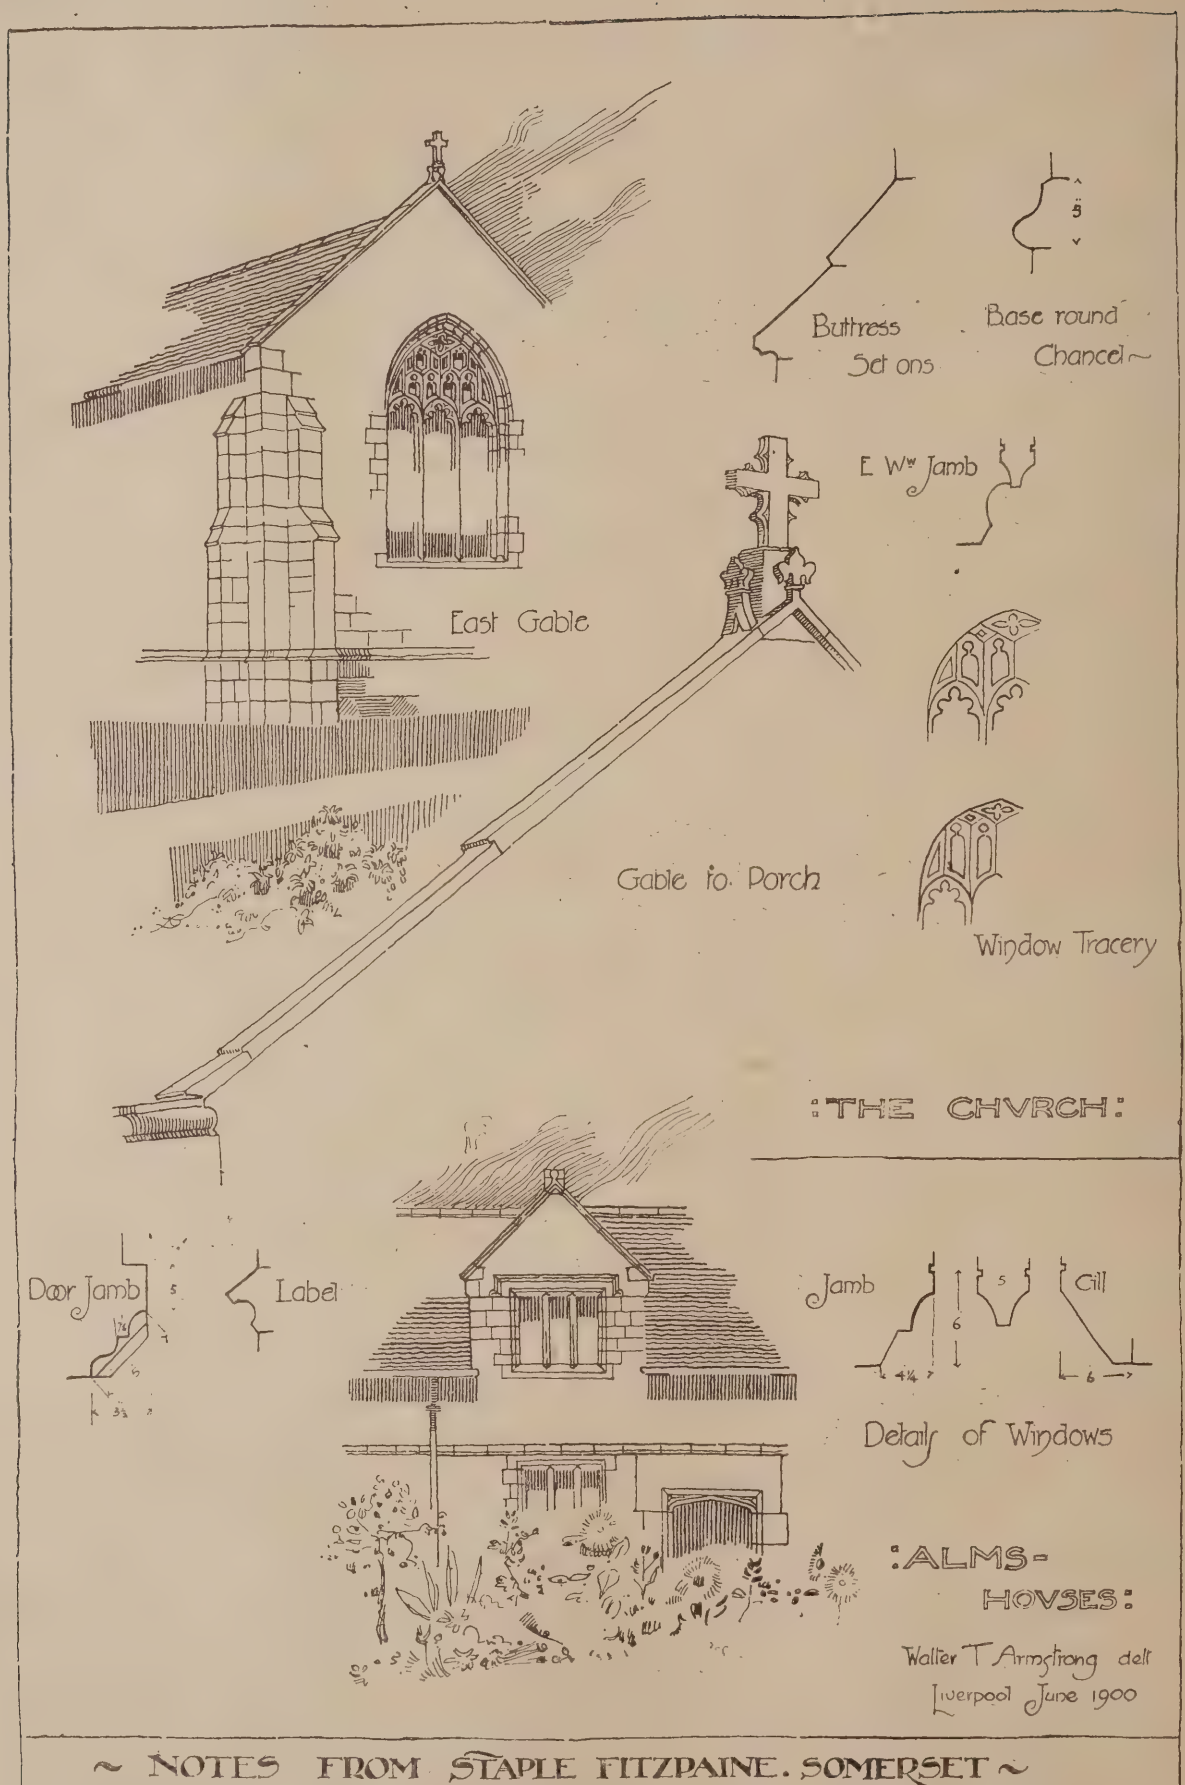
Wolvesey Castle.—It is proposed that the city of Winchester should purchase the ruins of Wolvesey Castle. Little now remains of this ancient fabric. It is asserted that Kincoils, first Christian king of the West Saxons, erected a castle upon this spot, but the present remains are Norman in their origin, as can be distinctly seen by the masonry, which has no Saxon peculiarities. The castle was dismantled by King Henry II., but must have been either reconstructed or extensively repaired, as it served for the residence of the bishops until it was destroyed by Cromwell, who only left the small fragment still remaining, which seems to have formed a portion of the Norman crypt. A modern palace upon part of the ancient site was begun by Bishop Morley in 1684, attached to a chapel of fifteenth-century date. The chapel still remains, but fire and other demolitions have left little of the palace, which was a fine structure in the style of Sir Christopher Wren—if it was not built by that eminent architect himself, as is frequently asserted. It is proposed that the park or grounds shall be thrown open to the public in August next, when the millenary of King Alfred will be celebrated.

The Central Fire Station at Bradford is now being erected.

The University College of South Wales.—The Cardiff Town Hall Committee have decided to recommend the Council to grant five acres of land in Cathays Park, free of cost, as a site for the proposed new buildings of the College.

A New Church at Weston Green, Thames Ditton, is in course of erection. At present only a portion of the building is to be proceeded with, at a cost of £1,460, so that the church will be capable of enlargement when necessary.

The Penrhyn Quarry Dispute.—Not a single Penrhyn quarryman complied with the invitation of the chief manager to resume work last Wednesday, referred to in our issue of last week, and the quarries have now been definitely closed. The migration of quarrymen continues unabated. Over seventeen hundred have already gone, and it is now stated that so determined are the men in the struggle that many who are tenants on the Penrhyn estate intend to give up their houses. A considerable number of men lately in Lord Penrhyn's employ have found work in South Wales and in Lancashire. It is estimated that from 1,200 to 1,500 have already left North Wales, while about 400 remain. Some of these, it is said, will shortly be engaged at a local slate quarry, which will be opened expressly to find work for them.



Christchurch Cathedral, New Zealand, still requires to be completed. The building was designed by Sir Gilbert Scott, and in 1881 the nave, with tower and spire, giving accommodation for 1,200 worshippers, was consecrated. As a memorial of the Jubilee it is now proposed to complete the building by adding the choir, sanctuary, transepts, and vestries, for which the foundations and walls have been provided. Upwards of £45,000 has been spent on the edifice, and it is estimated that about £15,000 will be needed for its completion. About £9,000 has already been collected.

The Church of St. Stephen, Westbourne Park, W., has been improved and enlarged. Built less than fifty years ago, it has already undergone many changes. Considerable structural alterations were effected in 1884 and 1888, but the present changes almost constitute remodelling. It was found that some parts of the sacred edifice were in a very bad state, and examination showed that the spire and roof were in a dangerous condition, while staircases and exits were little better. The arrangements and appearance of the interior were unsuited to modern requirements, and were even regarded by some as mean and shabby. The whole structure is now in a thorough state of repair. A new apse, altar, and reredos have been added to the chancel, a chapel for daily services, and a commodious choir vestry have been provided, the electric light has been installed, and many minor alterations have been effected calculated to add to the comfort of the worshippers. A number of gifts, including a new lectern and altar cross, have been presented by members of the congregation. The estimated expense of the work amounts to £6,764.

The Hull Property Committee at a recent meeting received a letter from Mr. Thomas Blashill, dated June 13th, accepting the appointment of consulting architect in connection with the competition for the proposed extension of the Town Hall. The sub-committee reported that they had discussed plans in connection with the Junction Street improvement, the formation of a square, and rebuilding of the Corporation property down to Chariot Street. The committee recommended that Engine Street be abolished, and that the block plan of the site submitted by the city engineer, as amended, be approved by the committee. It was resolved that the city architect be requested to consult with the various tenants with a view of ascertaining what accommodation they desired the Corporation to provide for them in rebuilding the property, and the city architect was asked to prepare and submit a rough scheme. It was also resolved that in the opinion of the committee it was desirable that a portion (facing the new square) of the upper floors of the new premises should be utilised for an hotel.

Bricks and Mortar.

APHORISM FOR THE WEEK.

So fair a church as this had Venice none:
The walls were of discoloured jasper stone
Wherein was Christos carved; and overhead
A lively vine of green sea agate spread.
CHAUCER.

Our Plates. THE illustrations of the churches of St. Bartholomew and St. Stephen form part of the article on "Ancient London" which begins on page 364 of this issue.—"A Glimpse of Bygone Days," by Mr. Sydney R. Jones, is a composition of sketches made at different times and places. The old-fashioned doorway, the creeper-covered wall shining in bright sunlight, and the surrounding objects which form the centre of interest are to be found within the cathedral close of Exeter, which city abounds in old-world subjects alike of interest to artist and architectural student. The small courtyard is approached from the roadway by a stone archway, which, while possessing good colour, is not favourable to a pen-and-ink sketch. Consequently this has been replaced by the one taken from quite another part of the country—Lapworth, in Warwickshire. When this method of working is adopted it should always be borne in mind that, though the details of the original study are altered for the sake of composition, the spirit and feeling should always remain the same.—Staple Fitz Paine is close to Taunton and the almshouses illustrated adjoin the church.

The late Mr. Francis Chambers. MR. FRANCIS CHAMBERS, architect, of 11A College Hill, Upper Thames Street, E.C., died on Saturday week last at the age of 71 years. The deceased commenced as a pupil of the late Sir Sidney Smirke, and was closely associated with the City throughout his long and useful professional career. He was a partner for nearly half a century in the firm of Dress and Chambers, architects and surveyors, whose offices were at 28 Queen Street. The name of the firm was subsequently changed to Francis Chambers and Sons, and it has been located on College Hill for many years. The deceased appeared in many important arbitration cases. He was concerned in the designing and erection of a great number of costly buildings, including those occupied by Cassell and Co., Limited, Messrs. Copestake and Co., Messrs. Pilkington Brothers, and Waterlow Brothers and Layton, Limited; St. Ann's Church, Hoxton; the schools belonging to the Central London School District at Hanwell; and the markets and Ladies' College at Guernsey. He was for many years the surveyor of the parish of St. James's, Garlickhithe, in which capacity he designed the present vicarage Upper Thames Street. The deceased also occupied many important appointments, being *inter alia* a surveyor to Her Majesty's Customs Fund and several building societies, a Fellow and a member of the Council of the R.I.B.A., and for many years an examiner of district surveyors in connection with that body. For some months past the deceased had been in indifferent health owing to heart trouble, a disease which he succumbed at his seaside residence, Cobo, Broadstairs, leaving to mourn his loss two daughters and one son, with whom he was in partnership.

New Elections to the R.I.B.A. THE following gentlemen have quite recently been elected to the membership of the Royal Institute of British Architects:—As Fellows: Messrs. Louis Ambler (London), T. P. Figgis (London), H. G. Garson (London), E. J. Jackson (Sydney, N.S.W.), C. E. Mallows (Bedford), and J. W. Simpson (London). As Associates: Messrs. S. Chesney (Stourbridge), G. E. Clay (Gravesend and Warrington), C. H. F. Comyn (London), F. Cooper (Feniscowles Old Hall, near Blackburn), C. A. Daubney (London), W. E. Emerson (London), J. E. Franck (London), A. R. Groome (Manchester), H. Haines (New Brompton), E. V. Harris (London), J. S. Heath (London), W. B. Hopkins (London and Great Berkhamsted), P. E. Nobbs (Edinburgh), S. V. North (London), C. W. Smith (London), W. H. Swann (London), A. Symon (London), A. M. Torrance, jun. (London), R. P. S. Twizell (Newcastle-on-Tyne), C. E. Varndell (London), and C. F. Young (London). As Hon. Associate: Mr. E. W. Smith, Member of the Royal Asiatic Society, Archæological Surveyor to the Government of India, N.W. Provinces and Oudh Circle, and Curator of the Lucknow (Government) Museum, Oudh; of the Museum, Lucknow, India; and Cheena Lodge, Naini Tal, N.W.P., India. As Hon. Corresponding Members: Messrs. J. Antoine Bouvard, Director of the Architectural Works of the Paris Exhibition, 1900; of 99 Rue de Verneuil, Paris; and L. C. Pedro d'Avila, hon. architect to the King of Portugal, architect to the Government, member of the Royal Academy of Fine Arts, Lisbon; of 41 Rue de Vasco da Gama, Lisbon, 2mo.

Overcrowding in Domestic Dwellings. LECTURING recently on this subject before the Sanitary Inspectors' Association, Mr. F. W. Morley summarised the causes of overcrowding as follows: The commercial conditions under which we live disturb the equal distribution of the population and cause the crowding together of the majority in certain centres which may happen to be convenient for carrying on certain industries, with the result that the law of supply and demand enhances the value of the land in these localities to such an extent that in order to secure a return for capital invested a larger number of buildings are erected on a given space than is proper. The great obstacle in the way of an efficient and final remedy of the problem, said Mr. Morley was the unsatisfactory state of the land laws. One outcome of the attempt at a solution had been the erection of various blocks of model dwellings. But there was something radically wrong with a system which rendered it necessary to crowd such a large number of persons upon a given area, when within a comparatively short distance large tracts of land were to be found vacant. Useful as model dwellings were, it was infinitely preferable, whenever possible, to provide cottage accommodation on the outskirts. After dealing with the various aspects of the question, Mr. Morley enumerated the following methods as capable of playing their part in the final solution: The provision of ample means of transit, the removal of factories from town to country, the erection of ample and suitable dwellings, the full use of the powers conferred by the Public Health Act, the Housing of the Working Classes Act, &c., the teaching of hygiene in public schools, and the taxation of the land in order to create a fund to be utilsed in cheapening the cost of the provision of suitable dwellings.

Types of Beauty. IF we want to form an idea of what bygone races were like, we must go to what artists have left; but, as the Hon. John Collier remarked when lecturing at the London Institution last week on "Varying Types of Beauty," artists are idealists, and cannot be depended upon. Did the Greek statue represent the true racial type of what the Greek man and woman wanted to be? That was the question. The fact of the matter was that everyone tried to become like the prevailing fashionable type, and the artists exaggerated the type. Egypt possessed the most rigidly conventionalised art, and yet an art in its earliest form singularly realistic, as shown by the famous figure of the Scribe in the Louvre. The remains which were left to us by the Greek sculptors showed us the elevated type created by Phidias. The lecturer showed on the screen photographs of many of the most famous statues and basreliefs of Egyptian, Assyrian, and Greek art, instancing the Venus of Milo and the Hermes of Praxiteles as among the greatest instances of ideal beauty. After the degenerate Roman and Byzantine times the Middle Ages had a poor ideal as regarded human beauty, but in Italy, where classical influences lingered, the type was always higher. The ideals of Botticelli, Raphael, and Michael Angelo were successively displayed; but it was Leonardo who created in his Monna Lisa a type of beauty which was more attractive than any of these; and following him, Luini perpetuated it. Everywhere in Europe, save in Italy, the ideal of beauty was always lower than that of the Greek Age, and the fact that at the time of the Renaissance the Italians were probably the handsomest race in Europe accounted for this. Coming down to Velasquez, Rembrandt, Van Dyck, and Rubens, whose portraits revealed but little actual beauty of racial type, Mr. Collier passed to the English school of the last century—Gainsborough, Romney, and Sir Joshua Reynolds—and the French school of Watteau, Boucher, Lancret, and Fragonard. The Frenchmen were not so much given to portrait painting, but their ideals were not high. And in modern times, was there an ideal of beauty at all? There was certainly great variety, and with the examples of the past ages it was possible that a great ideal might be attained. But we had not got it yet.

Forum Excavations: A Complaint. A CORRESPONDENT of the "Daily Graphic," writing from Rome, states that much surprise and dissatisfaction is felt there among archæologists that the Ingegnere Giacomo Boni should not be recognised in England as the author of the recent discoveries in the Roman Forum. On the occasion of the presentation of the gold medal of the Royal Institute of British Architects Mr. Emerson, the president, in giving Professor Lanciani high praise for his work and writings so well known among English-speaking people, also spoke of his having discovered the original Via Sacra and other monuments in the Roman Forum. Professor Lanciani has been on the Commission for the Works, but the excavations for the last two and a half years have been carried on solely by the Ingegnere Boni under the Italian Government, and the discovery of the original Via Sacra, the Lapis Niger, Fons Juturna, and Rostra of Julius Cæsar are entirely due to his extraordinary energy, indefatigable labours, and deep study of classic writers. It was for this that Ingegnere Boni was presented with the title of "Commendatore" by King Humbert, and by which he has earned the respect and high admiration of his confrères in Italy. Ingegnere Boni is a member of the Royal Institute of British Architects, was a pupil of Ruskin's, and has spoken in London, in English (in which he is fluent) on the architecture of Westminster Abbey, &c.

A Royal Residence at Rome. IT is stated that the vexed question of a residence at Rome for Queen Margherita has at last been decided upon, as the contract will shortly be signed for the purchase, for £100,000, of the Piombino Palace, so long the residence of the American Ambassadors, and two adjacent houses, all standing in large grounds in that part of the Eternal City known as the Ludovisi quarter. The palace is a modern building, the chief feature of which is a magnificent staircase, with a celebrated marble group, at the entrance, of Orestes and Electra, which is supposed to have stood in the gardens of Sallust, now belonging to the Piombino-Ludovisi collection. Above, there is a good-sized entrance hall hung with antique tapestry, which opens into a wide white-and-gold corridor, which runs the whole length of the palace, each wall being decorated with long mirrors from floor to ceiling, alternating with old family portraits set in as panels, with here and there a door, the whole set off by a red velvet carpet and innumerable varieties of palms, which grow so luxuriantly in Rome. Out of the corridor open many rooms, the chief of which is a gold-and-white ballroom. There is also a red-and-gold drawing-room, yellow-and-gold and blue-and-gold salons, followed by the dining-room, the *clou* of the whole. It is a square chamber of palatial proportions, with terra-cotta-coloured walls and an immense chimney-piece of black marble, veined with white. Above, as a frieze, is exquisite tapestry, representing hunting scenes in green, grey, and white, adding an air of richness and elegance to the apartment seldom attained in modern homes.

ARCHITECTURAL ASSOCIATION.

COLOUR IN ARCHITECTURE AS SEEN THROUGH AN ARTIST'S GLASSES.

BY A. WALLACE RIMINGTON.

A MEETING of this Association was held last Friday, Mr. W. Howard Seth-Smith, F.R.I.B.A., in the chair. The minutes of the previous meeting having been read and confirmed, Messrs. F. Baker and C. J. Goodwin were elected members of the Association. Mr. A. Wallace Rimington then read the following paper on "Colour in Architecture as seen through an Artist's Glasses":—

As a painter who has only studied architecture non-professionally, I felt some diffidence in addressing an architectural society upon an architectural subject; but as I have a great love for architecture, and have painted and sketched architectural subjects a good deal in Europe for a good many years past, I thought perhaps I might venture to make some few remarks to you upon colour in architecture from a painter's standpoint. Perhaps two further excuses for doing so might be found in the fact that most artists have to make a special study of colour, and that it seems to me the whole question of colour in art is at this moment of special importance.

We live at a time when from various causes the colour sense of civilised Europe has seriously deteriorated, and when, although there is some slight revival or new development of the feeling for colour amongst the cultivated few, it is, perhaps, becoming more and more weakened or obliterated amongst the great majority.

Taking a general view of Europe, and, excepting this partial revival, it is difficult to avoid the conclusion that in decoration, in costume, and in the thousand small objects of everday life,

Colour Tends to Disappear,

and, speaking broadly, where it remains, to become perhaps more crude and less harmonious. And this, I am afraid, also applies to some extent to the fine arts. There are a few good colourists amongst the artists of most countries; but, on the whole, good and powerful colour is becoming rarer in the great picture exhibitions of Europe, and those who have a keen and cultivated appreciation of it are confining their attention more and more to the old masters and to that very small modern school which attempts to carry on their colour traditions. Perhaps it may be said that I am overstating the case; but, if so, it is from no desire to do so, but because the conviction is forced upon me after a good deal of observation and in spite of the wish that it were possible to endorse the popular opinion as to a general advance of the feeling for colour in the decorative arts.

Compare the present condition of things with regard to colour with what it was in the later Middle Ages or in the full tide of the early Renaissance. Do we not go back to the remaining art fragments of these colour periods and study them with care and reverence, while we are almost hopeless of excelling them in refinement and strength? Does not the glass of Fairford and Trinity Chapel, of Chartres and Bourges, excite our admiring envy; and can we altogether reach the colour harmonies of the working handicraftsman who produced the enamels of Limoges, or the mosaics of St. Mark's, Ravenna, Monreale, and Cefalu?* Do not the early frescoes which are to be found in French and Italian† churches show a widespread feeling for good colour through the long periods in which they were produced, which is absent (in point of extension) at the present day? If further circumstantial evidence were necessary, one might enlarge upon the significant fact that it is in the out-of-the-way and little modernised parts of Europe that a pronounced colour sense still lingers amongst the people, like the few remaining leaves of orange and crimson of a once gorgeous autumn.

It is not, however, necessary to press the contention. Even assuming that the opinion is too pessimistic, it is better to see clearly the artistic dangers of our time rather than to underrate them. We shall at least lose nothing by being on our guard against

The Decay of the Colour Sense,

and we shall gain much by doing all in our power to stimulate and develop it. Whether we compare our present feeling in Europe for colour with what it was in the past or not, it is at least certain that it contrasts most unfavourably with what it has been for centuries past, and still is, in the East. There is, therefore, much room for improvement; and consideration of the whole question would seem not unadvisable.

And, further, in view of the part which colour plays in the economy of nature, and the fact that it is probable that it has some considerable influence not only upon our minds but upon our health, quite apart from its capabilities of giving æsthetic pleasure and pain, it can scarcely be denied that there are still vast opportunities for widening its use and making it a greater influence in our daily lives and in the art with which we are surrounded.

And in architecture, as the oldest and possibly the greatest of all the arts, the study of colour cannot, of course, be neglected. Whether we like it or not,

It must Come into Play

more or less in every building. All materials possess colour of some kind, and this colour directly affects the impression produced by a building. Moreover, the good effect of any architectural work, fine in respect of proportion, line and detail, may be completely destroyed by a vulgar colour scheme, with bad division of its colour masses or inartistic colour accentuation of unimportant parts; whereas, on the other hand, harmonious and refined colour may, as we all know, add immensely to its interest and dignity.

And now, before proceeding to the more practical part of this paper, there is one more proposition which I am sure most of you will agree with, namely, that the whole question of colour is surrounded with great and special difficulties. The condition of public opinion in England and in most European countries with regard to colour is almost chaotic, and although something is at last being done in America,* hardly any attempt is made to promote study of colour as that necessary

Part of Every Cultivated Man's Education

which some of us think it ought to be. Notwithstanding this, almost every one professes some taste in colour, and most people pronounce decided though divergent opinions about harmonies of colour and would consider it an insult if it were implied that they were not quite right about them, even though they might frankly confess to nearly total ignorance of, let us say, electrical science or musical composition. Colour is, however, quite as difficult to deal with as musical sound, and probably much more so. It is not easier to strike an absolutely true colour note than to sing a musical one, and the colour scale has a longer and more subtly-graduated range in point of ether waves than the musical one of air vibrations. The colourist has to stop his intervals upon a string a hundred times as long as that of the violinist, and he has often to strike a chord of colour with many more notes in it than a musical one, though if he be a great colourist he will produce it with unerring feeling and truth. Every good picture is, in fact, a series of such chords, carefully selected and combined, and perhaps we may venture to assert that every building ought also to be, even though its colour harmonies may be simpler.

This much at least we may say with some degree of certainty, namely, that every good architectural building ought to have some of the elements of a good picture about it, and that one of these elements is

Harmonious and Interesting Colour,

and, if so, then I would submit to you that it may perhaps be worth while for the architect to consider architectural design in the light of some of the more or less defined principles which guide the artist.

Upon the wider subject of these general principles I do not propose to enter to-night, but did time permit I should like to have included some general defence of such guiding canons in art and trace their development. I must, however, confine myself to saying that there is a certain broad general agrement as to some few of them. *Pace* a few extremists of the naturalistic school, all art has developed from what has preceded it, modified more or less, and sometimes very largely, by the study of nature. The artist, both from experience of what other painters have observed and selected from nature, and from nature herself arrives at some understanding of her laws. He studies other art works, and picks up a secret here and there from the pages of nature's great open book, and thus gradually learns something of how in her most beautiful effects she harmonises and emphasises her form and colour just as he discovers how she produces some of her effects of light and shade. Gradually also he learns that, when his picture is bad and out of harmony, it is because he has broken some one of those laws the necessity for the observance of which, I think, can even be traced into his own personal mode of artistic expression. Perhaps he is, to some extent, unconscious of this, and, like Turner, has not the power of putting his experience into words; but every painter, even though he may disown it, works more or less by the light of principles as well as mere feeling.

In two previous papers read elsewhere I have attempted to project the light of some of the more or less universally accepted canons or principles of

Composition in Painting

upon architectural design, and to-night I propose to refer very briefly to some of those connected with colour, and to submit the proposition to you that they also are in a greater or less degree applicable to your great art.

In dealing with the subject I find myself, however, in somewhat the same position that Ruskin did when he wrote "The Seven Lamps of Architecture" and had great difficulty to prevent their turning into thirteen; but as our time is very limited I must confine myself to a very few detached ones.

Let us, then, take as our first example that great open secret of nature in regard to good colour which is perhaps more neglected and less understood in these days than any other. I mean the natural law which, in any given coloured object under normal lighting, causes

The Richest Colour to be in the Half-tones.

The power of any colour-producing surface to absorb the vibrations which it abstracts from white light is limited. Thus, where white light falls most strongly upon an object, there its colour-producing powers will after a certain degree of illumination be most weakened, or, in other words, the balance of coloured rays which it gives off will be most diluted. On the other hand, when the light is less strong there will be less dilution and the colour richer. Take, for instance, a piece of drapery. It is quite evident that the richest colour is in its folds, or half-tones, and the weaker in its high lights, though these have the same colour-absorbing power and receive more light. In the deeper folds the colour is also still further increased by reverberation, like sound, in a reverberating space. In other words, the natural law is that the colour should be strongest in the half-tones.

Now, although, strange to say, the uneducated eye seldom appreciates this law, the great masters in painting, almost without any exception, have observed it most carefully, or, if you refuse to allow that they thought it out, at any rate they felt its action most strongly. Some of the early painters, whose colour is universally admitted to be of the most exquisite kind, combining strength with subtlety, and truth with decorativeness of the highest description, especially did so. Such painters, for instance, as Botticelli, Benozzi Gozzoli,

* For example: Church of the Jacobins at Toulouse, Cathedral of Amiens, St. Savin at Vienne, Cathedral of Chartres, Church of Montoise, and many others.

† San Francesco at Assisi, as a single instance.

* See "Instruction in Colour for Public Schools." L. Prang. "Class Book of Colour." M. Maycock. "Colour Work for Schools." H. P. Chace.

Fillipo Lippi, the Bellini, Perugino, and Titian even went as far sometimes as almost to bleach the high lights of their drapery, and, curiously enough, without taking special note of this, one is almost unconscious of the fact, which, instead of weakening their colour schemes, strengthens them.

Turning from the early to the later schools, whatever rank we may give Rubens in other respects, he was at any rate a splendid colourist. Here is what he says in his own words with regard to flesh painting:—"Paint your high lights white. Place next to it yellow; then red, using darker red as it passes into the shadows, then, with the brush filled with cool grey, pass gently over the whole until they are tempered and sweetened to the tone you wish." Finally, to step back at one stride from Rubens to early classic art in the few fragments of Greek painting that are left to us, the high lights are almost invariably but "faintly stained."* On the other hand, the bad painter, and especially

The Bad Modern Painter
